KILLINIQ FISHERIES PROJECT

PHASE I

Report by:

David J. Gillis and Marc R. Allard

MAKIVIK CORPORATION

RESEARCH DEPARTMENT

AUGUST 1984

Major funding for and services to this project were provided by Le Ministère de l'Agriculture, des Pêcheries et de l'Alimentation du Québec, Jean Garon, Minister; and L'Office de Planification et de Développement du Québec, François Gendron, Minister.

Additional funding and services were provided by Makivik Corporation, Mary Simon, President.

Funds to assist in training Inuit fishermen were provided by Employment & Immigration, Canada; Native Services, James Bay and Northern Québec region, Guy Tremblay, Director.

A. SUMMARY

This report summarizes the findings from Phase I of a feasibility study on the development of a commercial inshore marine fishery at Killiniq in northeastern Ungava Bay.

At a time when pressure is increasing to commercialize the renewable resource base as one means for expanding the cash economy of northern Québec, this study represents an attempt to guide development toward those species and geographic areas which are presently underutilized. In contrast to development efforts in the recent past, the orientation of this feasibility study is to consider presently unharvested marine species as the primary targets for commercial development. The existence of Atlantic cod (Gadus morhua) stocks, in particular, has been known in this area for several centuries and these have been periodically exploited by both natives and non-natives. Past commercial fisheries in the area, however, have been generally small, though this appears not to be related to the abundance of the resource.

The accumulation of the necessary field data to answer the feasibility question will take several seasons. Major funding and support for Phase I of the Killiniq Fisheries Project were provided by Le Ministère de l'Agriculture, des Pêcheries et de l'Alimentation du Québec and l'Office de Planification et de Développement du Québec, with additional funding and support from Makivik Corporation.

The primary objectives of the Phase I study were: to identify the distribution and abundance of Atlantic cod, Greenland halibut and other marine fisheries resources with commercial potential, that are seasonally available within a reasonable operational radius of Killiniq; to collect biological information pertinent to a commercial harvest of these species; to test the effectiveness of selected fishing gears that might be used by Inuit for the commercial harvest of these species with emphasis on those gears and technologies which could be readily introduced to native people; and to involve the Inuit in every aspect of the project, and particularly to train them in the specific skills required in a commercial fishery.

The field survey was carried out from July 19 to September 22nd, 1983. Two multipurpose fishing vessels were chartered for the exploratory fishing and outfitted with a variety of static gear types, the primary gears being gillnets and longlines. These gears were systematically deployed within the study area, and comprehensive set and catch data collected from all efforts. Standard biological measurements and samples were taken on commercial species, especially Atlantic cod. Fresh catches were processed and salt-cured at the operation's base and transported to southern markets at the completion of the field survey. A shore-based sampling program was established at Killiniq itself to attempt to monitor the temporal availability of Atlantic cod there.

Severe set and tidal currents precluded efficient sampling efforts in some sections of the study area, particularly in Ungava Bay, and a late cover of sea ice throughout the region shortened the intended field sampling period in 1983. These factors resulted in the need to delete from the sampling program the use of several secondary fishing gears. Because of the difficult conditions, planned environmental studies also had to be deleted. These deletions were made in order to protect the essential objectives of the feasibility study.

The results of the survey were encouraging. Though other commercial fish species were not found in abundance, the location of the Atlantic cod resource near Killiniq was re-established and catches were of commercial levels. The fish were uniformly large and represent a superior raw product for commercial use. Most catches were salted by standard methods and the resultant product was independently judged to be excellent by the Canadian Saltfish Corporation.

Comparison of the biological parameters of the present sample with those of a previous sample indicates either that the individual growth rate of the local cod has increased dramatically, or that the present concentration at Killiniq is related to the West Greenland cod stock. This important question must be addressed in future studies. Initial parasite analysis on this stock indicates that the codworm (Phoconema decipiens) is not prevalent.

This report recommends the continuance of studies toward the development of a fishery at or near Killiniq and based on the experiences of Phase I, provides direction for the design of future studies. Emphasis must be placed on the development of fishing gears and operational methods which are suited to the challenging physical conditions presented by the area. Further exploratory surveys in areas of the region that were not sampled during Phase I should increase knowledge of the spatial and temporal availability of the Atlantic cod resource. Several other species, in particular the Iceland scallop (Chlamys islandicus), warrant investigation with specialized gears. The cod resource near Killiniq should now be tested in an experimental commercial fishery to develop an efficient harvesting and processing system and to document the quantity of harvest which can be realized in such an operation. The involvement of local Inuit, the primary benefactors of any future fishery, should be maximized, particularly in the experimental fishery, to prepare them as fully as possible to assume responsibility in a commercial operation.

B. INTRODUCTION

The exploitation of renewable land, marine and freshwater resources has been, and continues to be, an essential element in sustaining the economy and culture of the northern Québec Inuit. Historically, the resources harvested were consumed directly as food, and many of the by-products were used in the production of clothing, shelter, travel equipment, tools and other implements or materials required for each season of the year. As contact with the outside world intensified, a process of commercialization developed and the inventory of important materials grew to include those produced locally and those imported from outside. Fur, skins, oil, ivory and occasionally food were exchanged with traders in order to acquire imported goods. This trading economy fostered the introduction of new technologies for resource harvesting, and gave rise to many profound changes in the material culture of Inuit. Trade and other commercial activities required to sustain this process became more complex and, over time, trade and barter gave way to an economic system based on cash and on the creation of more diversified opportunities for obtaining this cash. Today, the economy of the north is best described as a "mixed economy" comprised of subsistence activities, cottage industry, employment and transfer payments.

Cultural change in northern Québec has not replaced a strong reliance on the harvesting and consumption of local resources but it has changed the nature of this reliance. In recent years, the accelerated introduction of many other aspects of southern society has created additional needs for cash; needs which often exceed the ability of a local economy based almost solely on subsistence and domestic activities to provide. Consequently, there is increasing pressure toward the further commercialization of renewable wildlife resources as a means of expanding the local cash economy. As a result of the Inuit's traditional utilization of particular species, much of this pressure may be directed toward resources such as caribou (Rangifer tarandus caribou) and Arctic char (Salvelinus alpinus) which are already cornerstones in the subsistence harvest. These food

supplies are, however, increasingly required by an expanding population. It is prudent, therefore, to deflect the pressure to develop commercial harvests toward those species and geographic areas which are presently under-utilized in northern Québec. One promising example of such a resource is the Atlantic cod (Gadus morhua) stock which migrates seasonally into the marine waters surrounding Killiniq Island (Figure 1).

Inuit peoples have occupied the Killiniq area for centuries. Including both the northernmost Labrador and Ungava coasts, this area is widely recognized among Inuit for the abundant natural resources available there. Harp seals(Pagophilus groenlandicus), ringed seals (Pusa hispida), bearded seals (Erignathus barbatus), Arctic char, Atlantic salmon (Salmo salar) as well as many species of marine birds and waterfowl are all plentiful (James Bay and Northern Québec Native Harvesting Research Committee, 1979 and 1982). Caribou move periodically into the area in significant numbers and beluga whales (Delphinapterus leucas) inhabit adjacent waters. In 1976 and 1977, the population of Killiniq (then approximately 50 individuals) harvested 32,400 kg and 29,214 kg respectively of food (edible weight) from all species (Ibid.).

Killiniq (Inuttitut for "end of the land") is aptly named. It is a small island which lies just north of the tip of the Labrador Peninsula, near the southern side of the eastern entrance to the Hudson Strait. With such a strategic location the site has been known to European mariners since at least the mid 16th century. Mercator's map of 1569 would seem to indicate that Portuguese fishermen already knew of the area. John Davis (in 1587) and Weymouth (in 1602) visited the area before Henry Hudson gave his name to the adjacent waterway in 1610 (Dunbar and Hildebrand, 1952). With the subsequent development of the Davis and Hudson Straits into major marine exploration and supply routes to a vast portion of the southeastern and central Canadian Arctic, Killiniq became a key waypoint for a variety of marine traffic, and remains so to this day.

One of the first sustained visitations to the Killiniq area by outsiders was by the Dominion Government Hudson Strait Expedition which

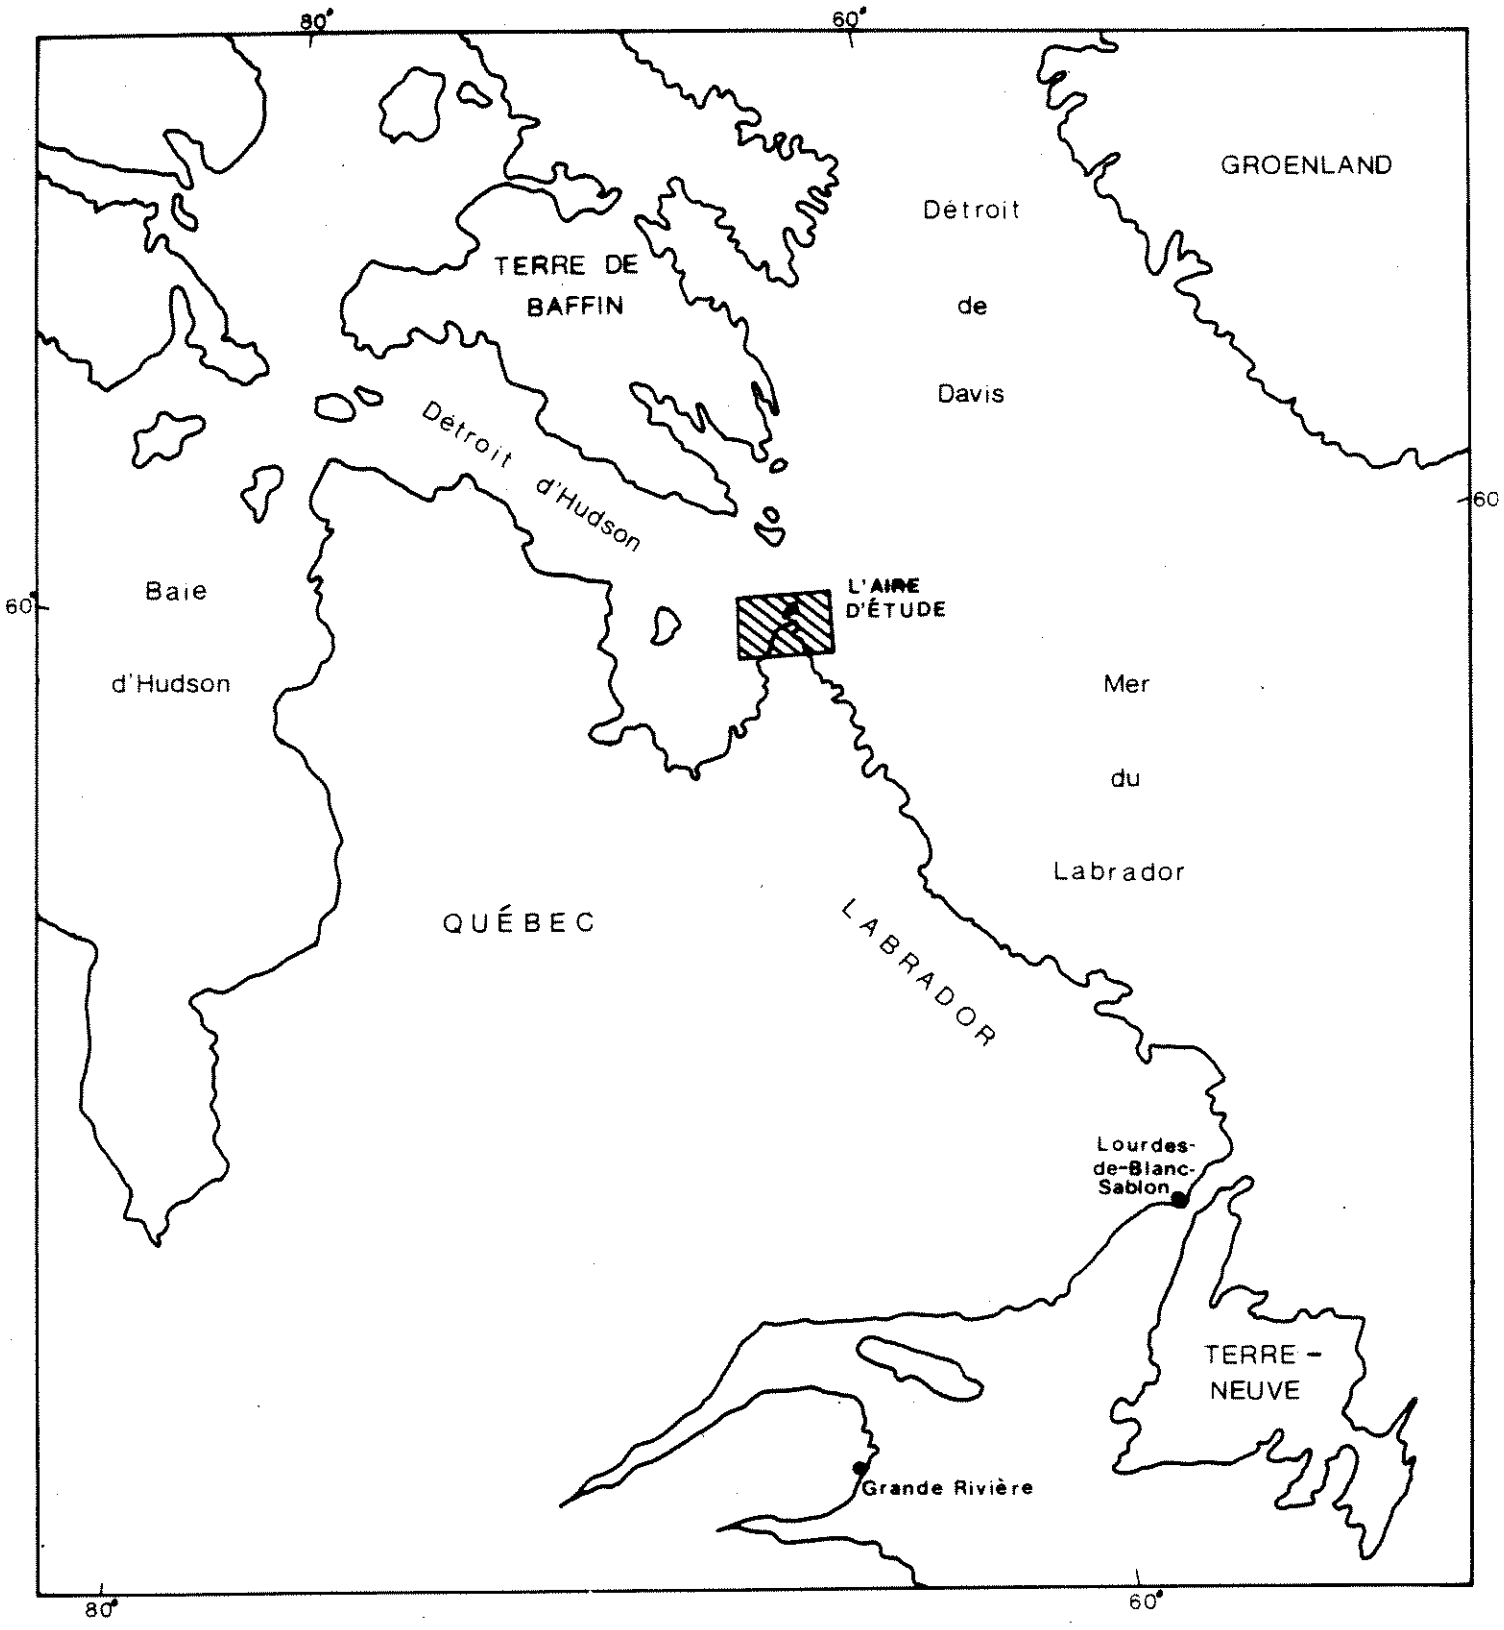

FIGURE 1: EAUX DE L'ATLANTIQUE ET DU SUD-EST DE L'ARCTIQUE
L' AIRE D'ÉTUDE ▨

established a meteorological station from 1884 to 1886 at what became known as Port Burwell. The history of the area from 1884 to 1971 has been summarized by Barnabe (circa 1971). By 1898, a Newfoundland fishing company, Job Brothers Ltd., was operating a cod "fishing station". This operation was taken over by Moravian missionaries in 1904 as they began educating and trading with the Inuit. The Hudson Bay Company established a trading post at Port Burwell in 1916 and the R.C.M.P. set up a post in 1920 to reaffirm Canadian jurisdiction in the Arctic and to collect customs duties from foreign vessels passing through the Hudson Strait to and from points to the west. These two institutions had replaced the trading role of the Moravians by 1924. Hudson Bay Company records of this period indicate that an organized Atlantic cod fishery was operating at Killiniq using both a cod trap and hand jiggers and barrels of cod were frequently sent out to other northern communities on passing ships. The R.C.M.P. and the Hudson Bay Company moved out of the area in 1936 and 1939 respectively.

The first critical study of Atlantic cod from the Killiniq area was performed by Vladykov (1933) on 12 specimens collected in 1927 by a Mr. Fritz Johansen. Between 1947 and 1950 and again in 1954, the Fisheries Research Board of Canada's research vessel, the "Calanus", was involved in biological and physical oceanographic studies in the Ungava Bay area (Dunbar and Grainger, 1952). Data collected included a detailed description of the Atlantic cod at Killiniq (Grainger and Dunbar, unpublished) which they had found to be abundantly available. As a result of this work, an experimental fishing project to provide cod as food to the Inuit was established in 1950 and 1951 (Ibid). Catches were apparently good, but the Inuit were adequately supplied in other food species such as seal and therefore apparently did not put much effort into utilizing this resource after the experiment ended (Evans, 1958).

Following an economic development survey of the Ungava Bay area by the Department of Indian Affairs and Northern Development (Evans, 1958) an economic development project began at Killiniq in 1959. Over the next several years, an Inuit cooperative was formed and fisheries for Arctic char and seals were started. The freezer building at the site today was

placed there in 1959, to store frozen fish. With the assistance of Economic Development Officers from the Department of Indian Affairs and Northern Development, an Atlantic cod fishery was developed to bridge the gap between the Arctic char fishery which usually closed in August and the arrival of migrating harp seals in October (Raymond Buffitt, pers. comm.). Landed catch records for cod have only been found from 1966 (8100 lb.), 1968 (60,000 lb.), 1969 (8,000 lb.) and 1972 (3,000 lb.) (Source: Government of Northwest Territories, Fish and Wildlife Service). The present fish plant (Photo 1, Appendix A) was constructed in 1968 but while it was ideally suited for an Arctic char fishery, the freezer facility was of a limited capacity for Atlantic cod products (Raymond Buffitt, pers. comm.). Cod landings were often restricted to what could be properly processed and stored. This multispecific commercial operation prospered, however, and as the settlement moved into the 1970's it was a flourishing Inuit community of over 100 people with a firm and viable economy based on the diversity and abundance of renewable resources available.

The decline of the community from that point until its abandonment in 1978 was a complex and controversial process; the intricacies of which fall outside the scope of this summary. Due to its remote location, modern services were difficult to maintain. As there was no suitable site for an airstrip, regular contact was possible only by float plane or helicopter except when a landing strip could be cleared on the sea ice between mid-winter and late spring. By August, 1977, the population had declined to less than 50 residents. Among those not already working, there seemed to be little interest in working at the fishery, so the commercial fisheries activities had effectively ceased (McAffee, circa 1977). There is no indication that the exodus of the population or the resultant collapse of the fishery was related to the availability of the resources. On February 8th, 1978, by Federal Government decree, the remaining residents of Port Burwell were moved to various northern Québec communities fringing Ungava Bay. Though the Department of Transport staffs a marine radio station at Killiniq on a seasonal basis, the town has been abandoned since that date.

The hunting areas adjacent to Killiniq continue to be frequented by the Inuit who come to hunt seals and to fish, particularly in the summer

and fall. The Killiniq Inuit have never accepted the closing of the settlement and a movement has developed to establish a new community in the area. A site on the Québec mainland some 40 km south of Killiniq has been tentatively identified and negotiations are presently underway between the Inuit and all levels of government.

It is therefore against this background of long and continuing interest in the Killiniq area and its resources, by native and non-native alike, that the present fisheries development project must be viewed. The purpose of the Killiniq Fisheries Project is to assess the feasibility of re-developing a commercial inshore marine fishery in northeastern Ungava Bay to be run by and for native peoples (Makivik Corporation, 1982). This is certainly not a new idea. As Dunbar (1952, 1970) has clearly pointed out, few areas within the southeastern Canadian Arctic support the diversity and abundance of potentially exploitable natural resources that are available at or near Killiniq. The commercial fishery which developed through the 1960's was successful for a time, before circumstances external to the fishery itself caused it to close. From a resource standpoint, the potential for development still exists at Killiniq, and it must be pursued. Given that harvestable resources are available, many options exist to overcome operational and logistical obstacles.

The present study is designed to further delineate and quantify, on a firm scientific basis, the potential offered by the marine fisheries resources of the area. In addition, it will investigate and test a variety of harvesting methods, product forms and production techniques, from which a feasible combination may emerge. Attention is being focused on those marine species which are not heavily utilized in present Inuit subsistence harvests. The logistical exercise of completing the program itself is a study into the related problems to be faced by a commercial venture at Killiniq and available methods for the movement of materials and products are being identified and tested as the program proceeds.

Phase I of the Killiniq Fisheries Project has focused on issues relating to the resources; relocation of previously known resources such as

Atlantic cod, and examination of as yet unstudied areas and species. In the process, however, much experience and data concerning the operational and logistical aspects of the program have been acquired. A number of Killiniq Inuit interested in reestablishing a fishery have been directly involved and have demonstrated both the attitude and aptitudes which would be required within a commercial fishery.

This document presents a detailed description of the Phase I methodologies, the operational, commercial and scientific data collected, and a discussion of those findings as they relate to the overall feasibility question. The main conclusion of this report is that the results of Phase I warrant the continuance of the program, and a set of recommendations are put forward to guide the development and realization of Phase II.

C. METHODOLOGY

1. GENERAL APPROACH

Phase I of the Killiniq Fisheries Project was primarily an exploratory survey to identify and study the potentially commercial marine fisheries resources available in northeastern Ungava Bay and adjacent waters. The study area straddled the Labrador Peninsula and approximated the reasonable radius of operations of a small (12 m - 17 m) fishing vessel (figure 2). Two such vessels (Photo 1, Appendix A) were chartered for the use of the project by the Ministère de l'Agriculture, des Pêcheries et de l'Alimentation du Québec. Various static gears, primarily gillnets and longlines, were deployed systematically within the study area, and comprehensive set and catch data collected from all efforts. Standard biological measurements and samples were taken on commercial species. Fresh catches were processed and salt-cured at the operations base and transported to southern markets at the completion of the field survey. A shore-based sampling program was established at Killiniq to attempt to monitor the temporal availability of the Atlantic cod resource at Killiniq.

Inuit fishermen were involved in most aspects of the program to train and familarize them in operational and processing techniques. At the completion of the survey program, biological samples were analyzed by various specialists. These and other results were then analysed and are presented in this report.

2. DETAILED METHODS

a) Study Area Description

Killiniq Island is located just north of the Labrador Peninsula and is separated from the mainland by McLellan Strait (figure 2). To the

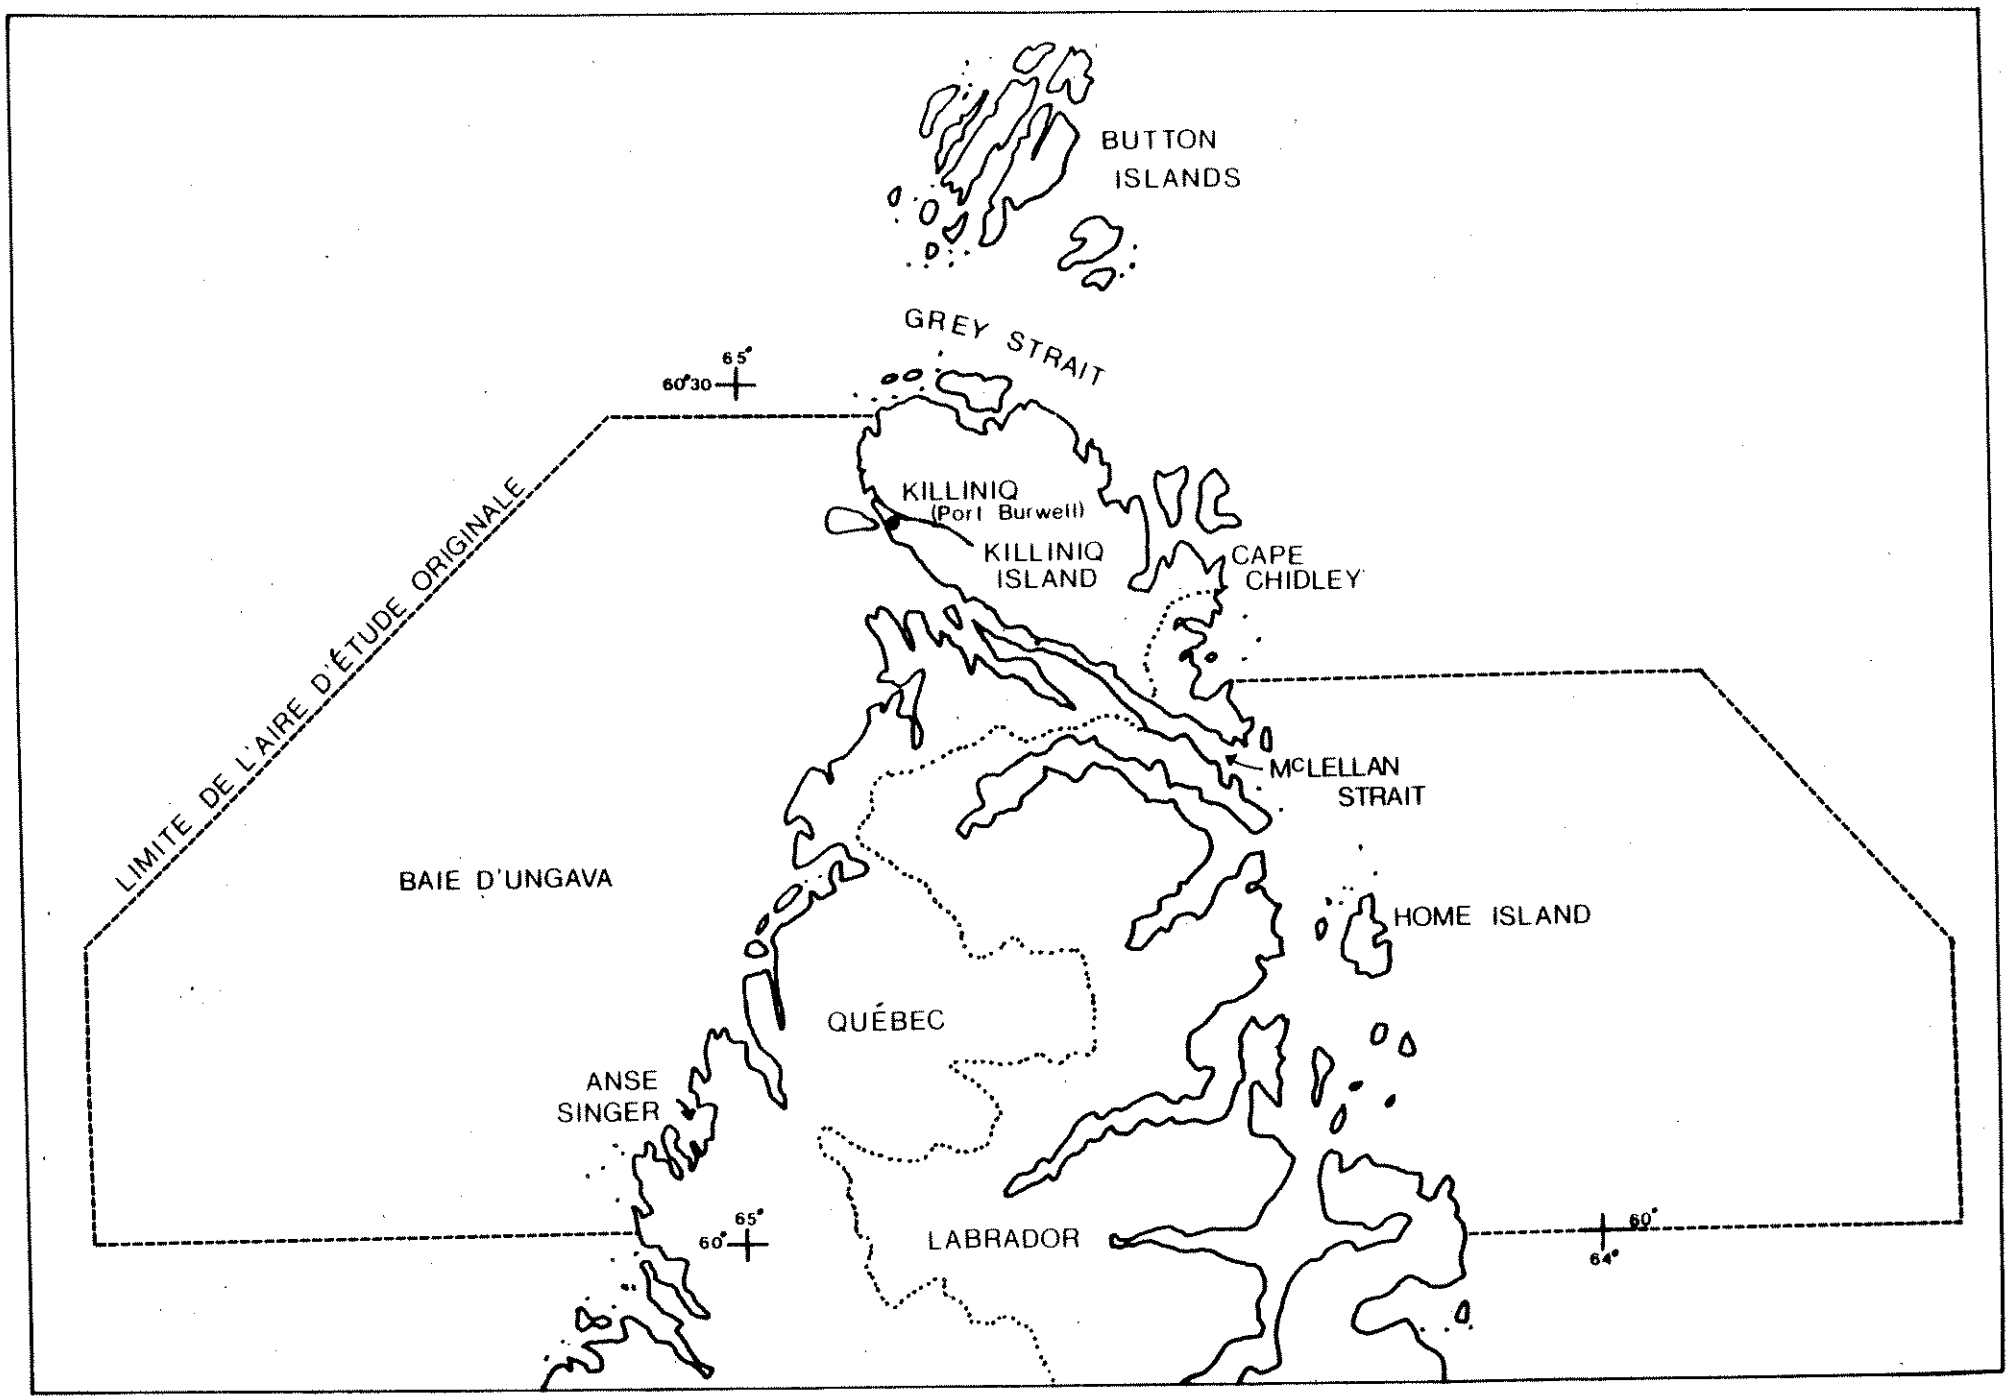

Figure 2: RÉGION DE KILLINIQ ISLAND - L'AIRE D'ÉTUDE

east of the peninsula is the Labrador Sea, to the west Ungava Bay. To the north lie the Button Islands and Resolution Island which, between them, form the eastern entrance to the Hudson Strait. The adjacent countryside is very rugged being the northern limit of the Torngat mountain range. In many areas steep cliffs rise out of deep inshore waters. The highest point of land on the island is 537 meters. The Killiniq settlement site is located on the southwest side of Killiniq Island at 60°25' N 64°50' W. Terrain near the settlement is still very rugged (cover photo) but the hills are lower, attaining heights of 30 m - 150 m. Available bathymetric information is given in Appendix J.

The dashed line in Figure 2 represents the boundary of the study area. This area was further subdivided into a grid of small blocks of equal size, each block being 5' of latitude by 10' (approximately 5 square nautical miles). There were 18 and 22 such blocks on the Labrador and Ungava sides respectively (see key map, Appendix C).

b) Materials and Equipment

i) Vessels

Two multipurpose commercial fishing vessels were chartered and brought from their home port at Lourdes-de-Blanc-Sablon to Killiniq for the field program. The larger vessel, "F/V Silver Condor" (photos 2, 3 and 5, Appendix A), was a 16.7 m stern trawler which was adapted to handle gillnets by utilizing the overhead trawl net drum. This vessel also featured a refrigerated/frozen storage hold. The smaller vessel, "F/V Cindy Rogers" (photos 2, 3, 6, Appendix A), was a purpose-built gillnetter/longliner, 12.2 m in length. Technical descriptions of these vessels and the equipment onboard each are given in Table 1. A list of equipment placed onboard each vessel for the duration of the project is given in Table 2.

An 8.5 m open trap boat (photo 1, Appendix A) was also rented and brought to the site to tend shore-based and other local gear. Several local Inuit canoes were used periodically for general duties near the operations base.

Other	- 5 survival suits	- 7 survival suits - 500 m x 48 mm hydrographic wire (existing winch) - auxiliary freezer unit for hold

(ii) Fishing Gears and Scientific Equipment

A comprehensive collection of primarily static fishing gears was assembled for the field studies, the details of which are given in Table 3. The longlines, commercial cod gillnets, surface gillnets, trammel nets, experimental nets and crabpots were assembled from their components at the M.A.P.A.Q. Regional Laboratory at Grande Rivière under the supervision of Mr. Arthur Mauger. Other fishing gears were purchased or rented. A large collection of spare pieces and repair materials for these fishing gears was on hand. Scientific sampling equipment (Table 3) was borrowed from McGill University in Montréal and GIROC.

c) Operations

(i) Project Itinerary

The Killiniq site was visited by two Makivik project members and two M.A.P.A.Q. personnel in February 1983, to inspect the condition of the facilities and detail the modifications and installations which would be required for the project. Immediately following, consultations and discussions concerning the project were held with former residents of Killiniq and others in all the Ungava Bay Inuit communities. Concrete preparations for the accomplishment of the Phase I study design began on April 20th, 1983. Key events marking the progression of the activities are outlined in Table 4. Mobilization of the two chartered vessels in late July in Grande Rivière coincided with the preparation of the base at Killiniq. A detailed itinerary of the voyages of the chartered vessels is given in Table 5 (a and b). Fritz Axelson on behalf of M.A.P.A.Q. and Raymond Buffitt on behalf of Makivik Corporation accompanied the vessels to and from the study area. The commencement of field sampling, scheduled for August 4, had to be delayed to August 19 due to lingering sea ice over the study area. Attention was focused initially on the Labrador side of the study area, however, once the Ungava side cleared of ice, all subsequent sampling was directed there. Exploratory fishing and other field sampling was completed

TABLE 3 - LIST OF FISHING GEARS AND SCIENTIFIC EQUIPMENT ASSEMBLED FOR THE FIELD STUDIES

KILLINIQ FISHERIES PROJECT, PHASE I

#	FISHING GEAR
12	Longlines; No. 28 line with hooks of #13, #15, #6283, #6284
40	Bottom cod gillnets; commercial type # 14 monofilament, mesh size 5½", 6" and 7", 50 fathoms length (hung), 25 meshes deep, double selvage
5	Surface gillnets; # 14 monofilament, mesh size 5½" and 6"
1	Cod Trap: circumference 52 fathoms, depth 10 fathoms mesh size 3½" and 5½", 35 fathom leader
1	1 Autofisher; automatic jigging machine
15	Crab Pots; 1.5 m x 1.5 m x 0.6 m, box type, 82 kg each
10	Lobster pots; standard wood lathe construction
17	Trammel nets: outside panels mesh size 16" inside panel mesh size 2½"
12	Experimental nets; geometric progression (approx.) of mesh sizes: 1", 1.5", 2", 2.5", 3", 4"
8	Hand line and jigs; Newfoundland and Norwegian types
	SCIENTIFIC EQUIPMENT
8	Niskin bottles: 5 litre capacity
2	Bathyothermograph: 0-60 m
1	Epibenthic sled: 1m x .75 m x .25 m mesh size 2.00 mm
3	Zooplankton Ring Nets; meshes: .233 mm, .500 mm and 1.00 mm

by September 15, the two survey vessels left the site on the 16th, and the base was shut down and vacated by September 22. Having made the trip south, stopping at Lourdes-de-Blanc-Sablon to sell the fish product and at Grande Rivière to demobilize, the vessels went off charter on October 13.

Laboratory analyses of the retained biological samples began almost immediately. Final analysis of the data cumulating in this report was underway in January 1984. A draft final report was presented in April 1984.

(ii) Base Preparation

The required alterations and repairs to onsite facilities were identified during the site survey in February, 1983. Immediately prior to the field season the following modifications and installations were made. Four houses were refurbished to minimally acceptable standards to accommodate study personnel. One building was extensively refitted as a cookhouse. In all five houses the roof was repaired, new windows and oil heaters were installed, and the interiors were cleaned and painted. The cookhouse was fitted with a water pump and heater. Power was supplied by a 6.0 kw generator installed in an adjacent building.

Extensive repairs were also required at the fish plant site. The more modern of the plant buildings are constructed of steel and concrete and were structurally sound although most of the mechanical equipment left at the site was beyond repair. The processing plant was thoroughly cleaned and the floor and ceiling painted. The freezer roof was repaired and a small area partitioned off and fitted with a freezing unit for bait and food storage. An oil heater was installed and a small office/lab built in the old fish plant, the remainder of which was used as a gear workshop. On the wharf, all rotting planks were replaced and a whole section washed away by ice was rebuilt. All buildings on the site were rewired by an electrician to meet the project's requirements. Other installations included: a hoist and boom on the wharf for loading and unloading the vessels, a seawater supply system for washing fish and equipment and two small

(6.0 kw) generators to supply power to the plant site. One important installation was that of a fuel line from the reservoirs to the wharf area for refueling the vessels.

(iii) Material Logistics

The materials, equipment and supplies needed for Phase I were delivered to the site by various means. The majority, (including food, 20 metric tons of fishery salt, all materials for base preparation, most fishing gear and scientific equipment) was shipped to the site in early July on the MOT icebreaker "C.C.G.S. Des Groseilliers". The two chartered fishing vessels brought the remaining fishing and scientific equipment from Grande Rivière, Québec. Seven thousand pounds of frozen herring for bait was carried to the site aboard "Silver Condor".

Access to the site in the early period of the field program was arranged with MOT who were operating a BELL 212 helicopter in the area. Once ice conditions permitted, further deliveries of personnel, fresh food, parts and mail were made by a single-engine plane on floats chartered out of Kuujjuaq, Québec as required.

At the completion of the study, some of the equipment and all of the fish products were carried south by the two chartered vessels. Remaining gears to be shipped south were picked up by the "C.C.G.S. Des Groseilliers" in late September and delivered to Québec.

(iv) Sampling and Documentation

The exploratory procedure initially used during field studies was to deploy different types of fishing gears from each of the two vessels within one or several adjacent sampling blocks. The two vessels always worked in the same general area to assist and advise the other if necessary. Generally, gillnets were set at each location overnight. Longlines were, in some instances, retrieved within several hours but at other times left overnight as well. Although major modifications to these procedures

were subsequently required (sections D.1.d, D.1.c and E.2), the catch sampling and documentation procedures outlined below were followed throughout the study.

For every effort involving each gear, detailed records were kept of the block number, precise location, gear type and size, duration, water depth and damage. Each potentially commercial species was counted and/or weighed. For commercial species, length frequencies for each sex were recorded to the nearest cm. Random sub-sampling was performed only where large catches dictated to do so.

Further biological data was collected by detailed autopsies of selected fish. Autopsies included total length to the nearest mm, round weight to the nearest 100 grams, sex and state of maturity. Otoliths were removed from all autopsied fish for age determination. The parameters documented from autopsied fish were corrected against the random length frequency distribution to calculate that parameter on the total catch. The stomach contents of eighty fish and internal parasites of approximately forty others were retained for analysis.

(v) Laboratory Procedures

The ages of the individual fish were determined from otoliths. The otolith was sectioned with an ISOMET low speed saw as close to the center as possible so as to expose the nucleus. Half of the sectioned otolith was placed on a hot plate for approximately 15-20 seconds, at a temperature of 260°C to 480°C, depending on the size of the otolith. The burnt sections were then placed upright in a tray and read under a microscope using reflected light.

Stomach samples were examined and identified to species where possible and the frequency of their occurrence calculated. The parasite samples were examined for species composition.

(vi) Production

Most fresh catch of commercial species collected during Phase I was processed following standard commercial techniques. After biological sampling and documentation was completed, the fresh fish were gutted, headed and split (removing the backbone). Split fish were then cleaned and lowered into the hold of the "Silver Condor" where they were layered alternately with salt. This salted product was brought south at the end of the field season, where it was graded and sold to the Canadian Saltfish Corporation at Lourdes-de-Blanc-Sablon.

D. RESULTS

1. OPERATIONS

a) Sea Ice

Sea ice was abnormally late clearing out of much of the eastern Canadian Arctic in 1983 (figures 3, 4, and 5) and access to our Phase I study area (figure 2), both in Ungava and Labrador, and to Killiniq itself, was directly affected. Up until the 19th of August (figures 3 and 4) with only two short interruptions, the ice pack remaining in Ungava Bay was pushed against the coast in the Killiniq area. A narrow band of water along the eastern shore remained clear from approximately July 15th to July 23rd and the Killiniq area itself was sufficiently clear on August 12th to allow the study's chartered vessels, which had been delayed by ice at Home Island (figure 2) since August 4th to proceed to the site (Table 4). By August 19th, the vessels were able to move out of Killiniq but loose strings of ice persisted in Ungava Bay, jeopardizing any static gears which might be set there. On the coast of Labrador from August 20th to 23rd, ice was also present though the vessels were usually able to manoeuvre around it. Gears could be set and retrieved but not without risk as some gears were lost to ice during this time. By August 23rd at Killiniq, all but the shore-stranded sea ice had gone and Ungava Bay was clear. Sea ice was not a factor in the execution of the exploration program after this date.

The direct effects of these conditions on the planned exploratory program were quite significant. Commencement of effective exploratory fishing was delayed by approximately 21 days by ice and this precipitated the request (subsequently granted) for an extension of the field sampling period. Several sets of static fishing gears were lost to ice during initial sampling attempts and several others sustained damage.

b) Weather

Weather in the study area during Phase I was quite suitable for the operation of the two survey vessels. Only three days of sampling time were lost exclusively because of meteorological conditions, excluding ice coverage. Details of recorded meteorological measurements made by MOT personnel at Killiniq are found in Appendix B.

A monthly summary of some key meteorological parameters at Killiniq during the field studies period is given in Table 6. Temperatures were slowly cooling through the period. Precipitations were quite low, totalling 180.5 mm for the three months. In July, wind directions were evenly split between all quadrants except for a low occurrence of NW winds, which were infrequent throughout the whole period. Winds from the two southerly quadrants, SW and SE, prevailed through August and September (Table 6). Wind velocities were almost invariably light to moderate through the whole summer, with few observations of winds in excess of 20 knots (39 km/hr).

c) Tidal and Set Currents

Similar to all of Ungava Bay, the northeastern coast features a semi-diurnal tide of considerable, if somewhat variable, magnitude (figure 6). This is manifested in strong tidal currents over much of the Bay, but particularly so where waters are deflected around coastal headlands and nearshore islands. These fluctuating tidal currents are superimposed upon a steady set current which brings water from southern Ungava Bay in a northeasterly flow between Akpatok Bank and the northeast coast of the Bay (figure 7). As a result, forceful water movements and turbulent water were encountered over all but the most sheltered coastal areas in the Ungava study area. The dominant hydrological feature of the Labrador study area is the Labrador current, which sets in a generally southern direction parallel to the coast. Tidal ranges on this coast are of less magnitude than in Ungava Bay, although narrow coastal passages are swept by strong tidal currents.

TABLE 6 - MONTHLY SUMMARY OF KEY METEOROLOGICAL PARAMETERS AT KILLINIQ JULY TO SEPTEMBER 1983 (SOURCE: ENVIRONMENT CANADA, CANADIAN CLIMATOLOGICAL CENTRE)

(Adapté de Dunbar (1951) et Gustajtis & Buckley (1977))

These currents and tides had a direct impact on the success and effectiveness of the survey activities in the study area, as detailed in section d).

d) Operation of Fishing Gears and Vessels

Both the vessels employed during the field studies of Phase I were adequately suited to their roles in the program and their crews were competent in the operation of the vessels and their gears. The smaller (12.2 m) vessel was particularly well suited to working very close inshore, being highly manoeuverable and having a shallower draft (1.0 m).

The severe physical conditions encountered in the study area, particularily the set and tidal currents, had a significant impact on the operation of the static fishing gears used during the project. Much of the Ungava Bay study area could not be effectively surveyed, as the strong currents damaged or swept away both longline and gillnet sets (Photo 4, Appendix A). Respite from these currents was only available in well-protected inlets and coves along the coast but at many of these locations, heavy beds of seaplants (probably Laminaria sp.) fouled the gears. As a result of this, damages to and losses of gears were initially quite high. This situation improved considerably once efforts became concentrated along the south and west coasts of Killiniq and Jackson Islands (figure 8). Here, through very strong currents swept just offshore, a number of protected coves were found where nets could be set close inshore in relatively still water.

Operationally, the situation on the Labrador coast was somewhat better. Here, effective deployment of gears was generally uninhibited by the currents, although extremely heavy beds of seaplants were encountered in some locations. Prevailing currents along this coast (figure 7) tend to bring loose ice pans and strings of ice through these waters from areas far to the north in Davis Strait and west in Hudson Strait. With favourable winds (offshore), disruptions would be limited to waters well away from the

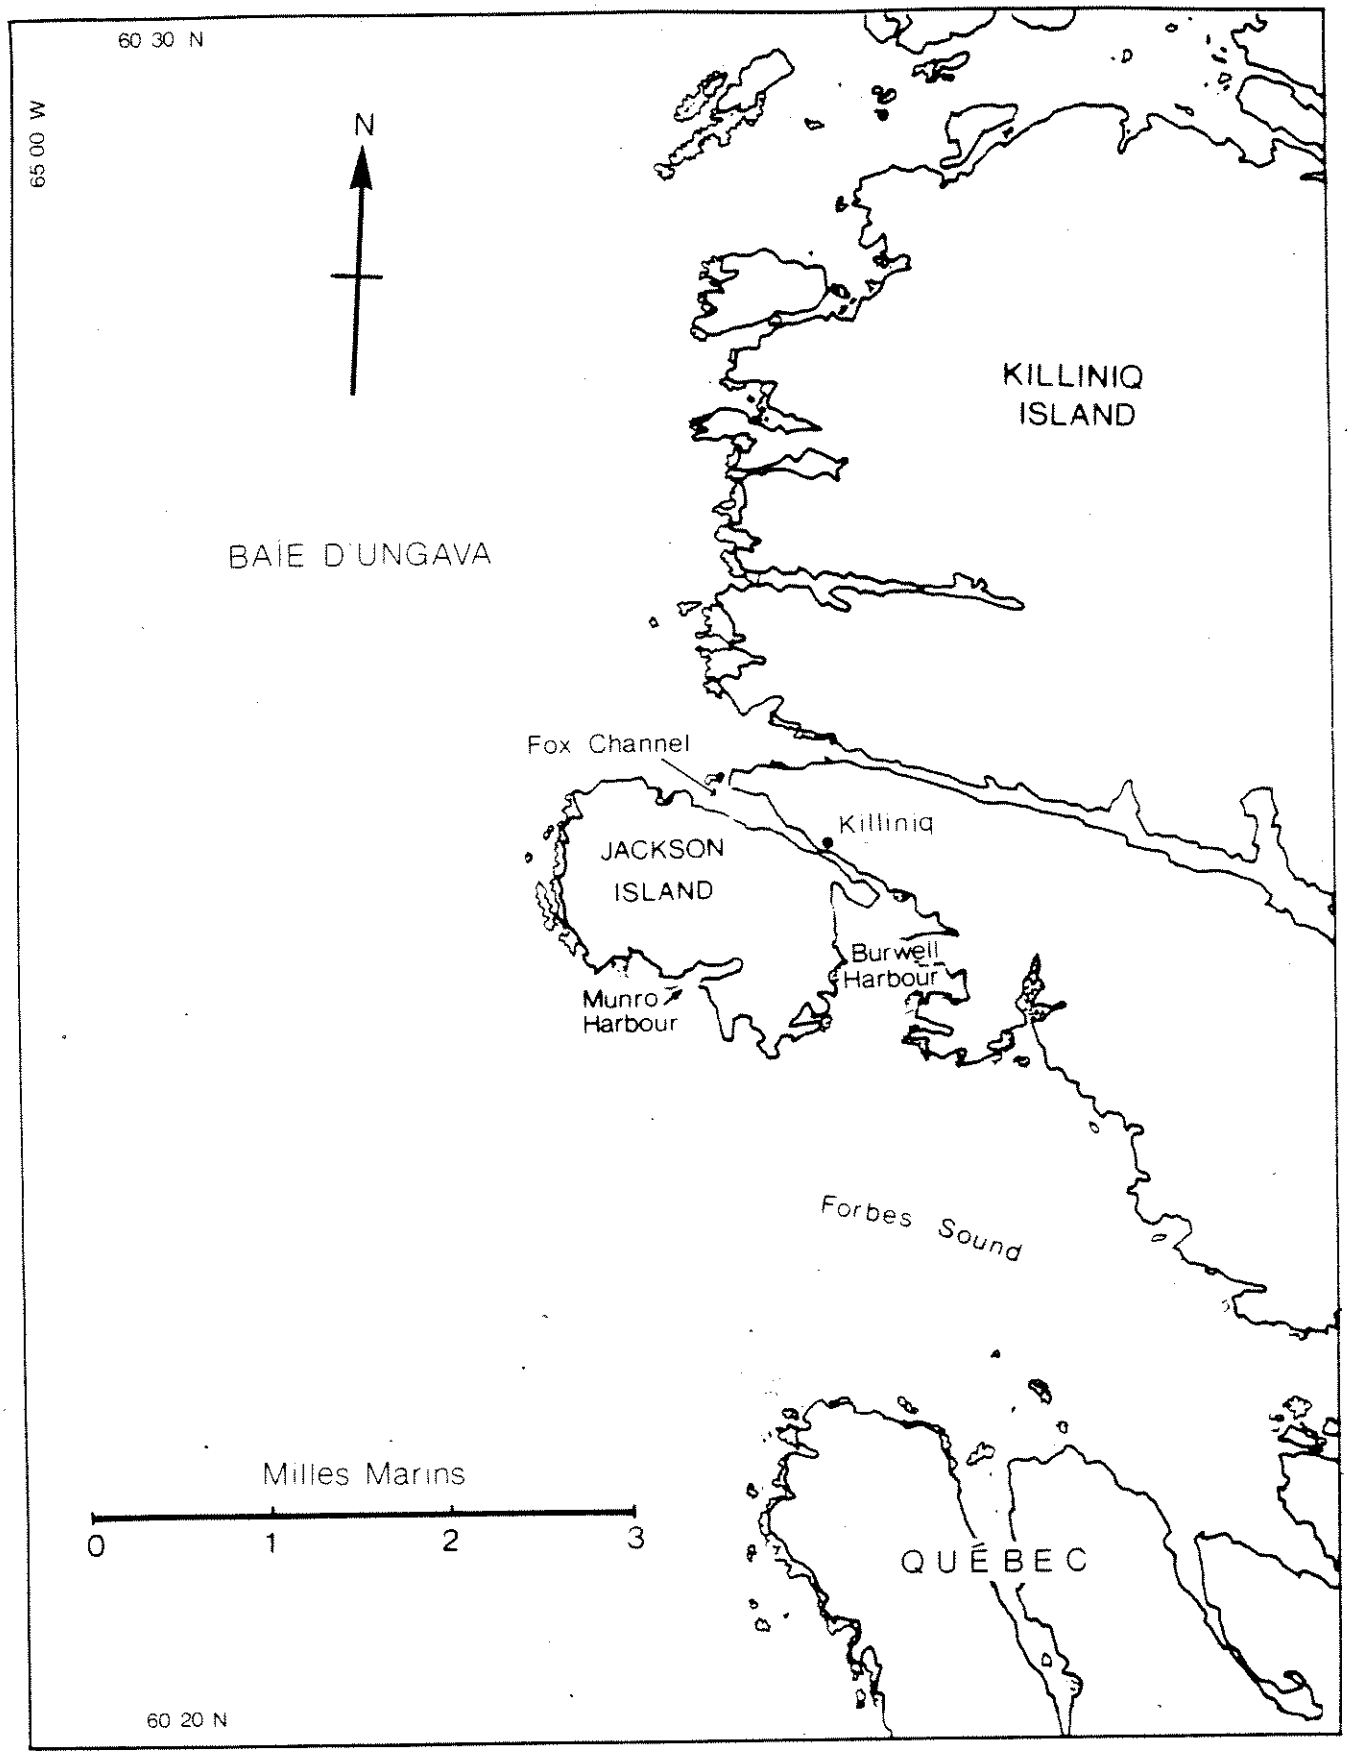

FIGURE 8 : ENVIRONS IMMÉDIATS DE KILLINIQ

coast. However, onshore winds may drive any loose ice in among the coastal islands and into the outer reaches of the fjords, as was observed in Phase I.

In the initial stages of the survey, longlines and gillnets were both deployed. The longlines sets were found less susceptable both to damage from currents and fouling by bottom flora. However, the herring baits, which were of good quality, were lost from the hooks quite quickly, seemingly in less than two hours. It is thought that the combination of large numbers of small benthic scavengers (primarily amphipods) loosening the bait and the action of the hooks against the bottom caused by the currents contributed to this phenomenon, even when the trawl line was buoyed. Once gillnet catches of Atlantic cod increased greatly with no corresponding improvement in the performance of the longlines, the latter were retired in favour of the more efficient nets. Upon examination, it was apparent that the cod caught in this area were gorging on an abundant supply of natural bait (section D.3), which would reduce the effectiveness of baited gears in any case. To this point in time, the "Cindy Rogers" had been used primarily for longlining and the "Silver Condor" for gillnetting. After discontinuing use of the longlines and rigging the "Cindy Rogers" for gillnets, most of all subsequent fishing operations were completed from this vessel, and the "Silver Condor" became the focus of sampling and processing activities (Photo 5, Appendix A). Retrieval of gillnets using the overhead trawl-net drum of "Silver Condor" had been resulting in some damage to the nets; due at least in part to the small diameter of the drum. The "Cindy Rogers" was more suitable both for handling gillnets and working in the extreme inshore fishing locations near Killiniq (Photo 6, Appendix A). Also, with the nets available reduced to approximately one half the original total and those fishing sites being surveyed situated immediately adjacent to the operations base, one vessel could easily handle the sampling workload.

Crab pots were deployed a total of five times early in the program, in the deeper offshore areas of Ungava Bay and along the Labrador coast. Where currents were strong, the heavy (5/8") haulup ropes were very susceptible to sinking even though they were well buoyed (Photo 4, Appendix

A). Once efforts became directed at the close coastal areas near Killiniq, exploratory crab fishing was discontinued.

e) Study Area Coverage

The ship time lost while sea-ice covered this area and the damaging effects of currents on the fishing gears had the combined effect of reducing that portion of the original study area that was actually surveyed during Phase I (figure 9). Only four days of effort with both vessels was directed at the Labrador side of the study area. These efforts were, however, spread over a variety of locations from inside the coastal fiords to some 18 nautical miles offshore. In Ungava, six sea-days were directed at the study area south and west of Killiniq Island, however, the currents in these areas made effective deployment of the gears difficult and sometimes hazardous. After August 30th most efforts were directed at a small area around the western end of Killiniq Island. Here, where a number of small coves faced a deep (up to 70 fathoms) channel just offshore, nets could be protected from the currents. Within this small area, a good number of sites suitable for nets were identified through the experiences of fourteen days of applied fishing efforts.

The deployments of a number of the gears, including the automatic jigging machines, lobster pots and experimental nets, which were planned were not possible due to physical and temporal constraints. Most of the planned environmental sampling program was dropped for the same reason. While the information and experience lost because of these deletions was regrettable, they were required to ensure that the primary gears (commercial gillnets and longlines) were adequately tested and to maximize the areas which could be surveyed with those primary gears.

Detailed information collected to describe each exploratory effort is presented in Appendix C.

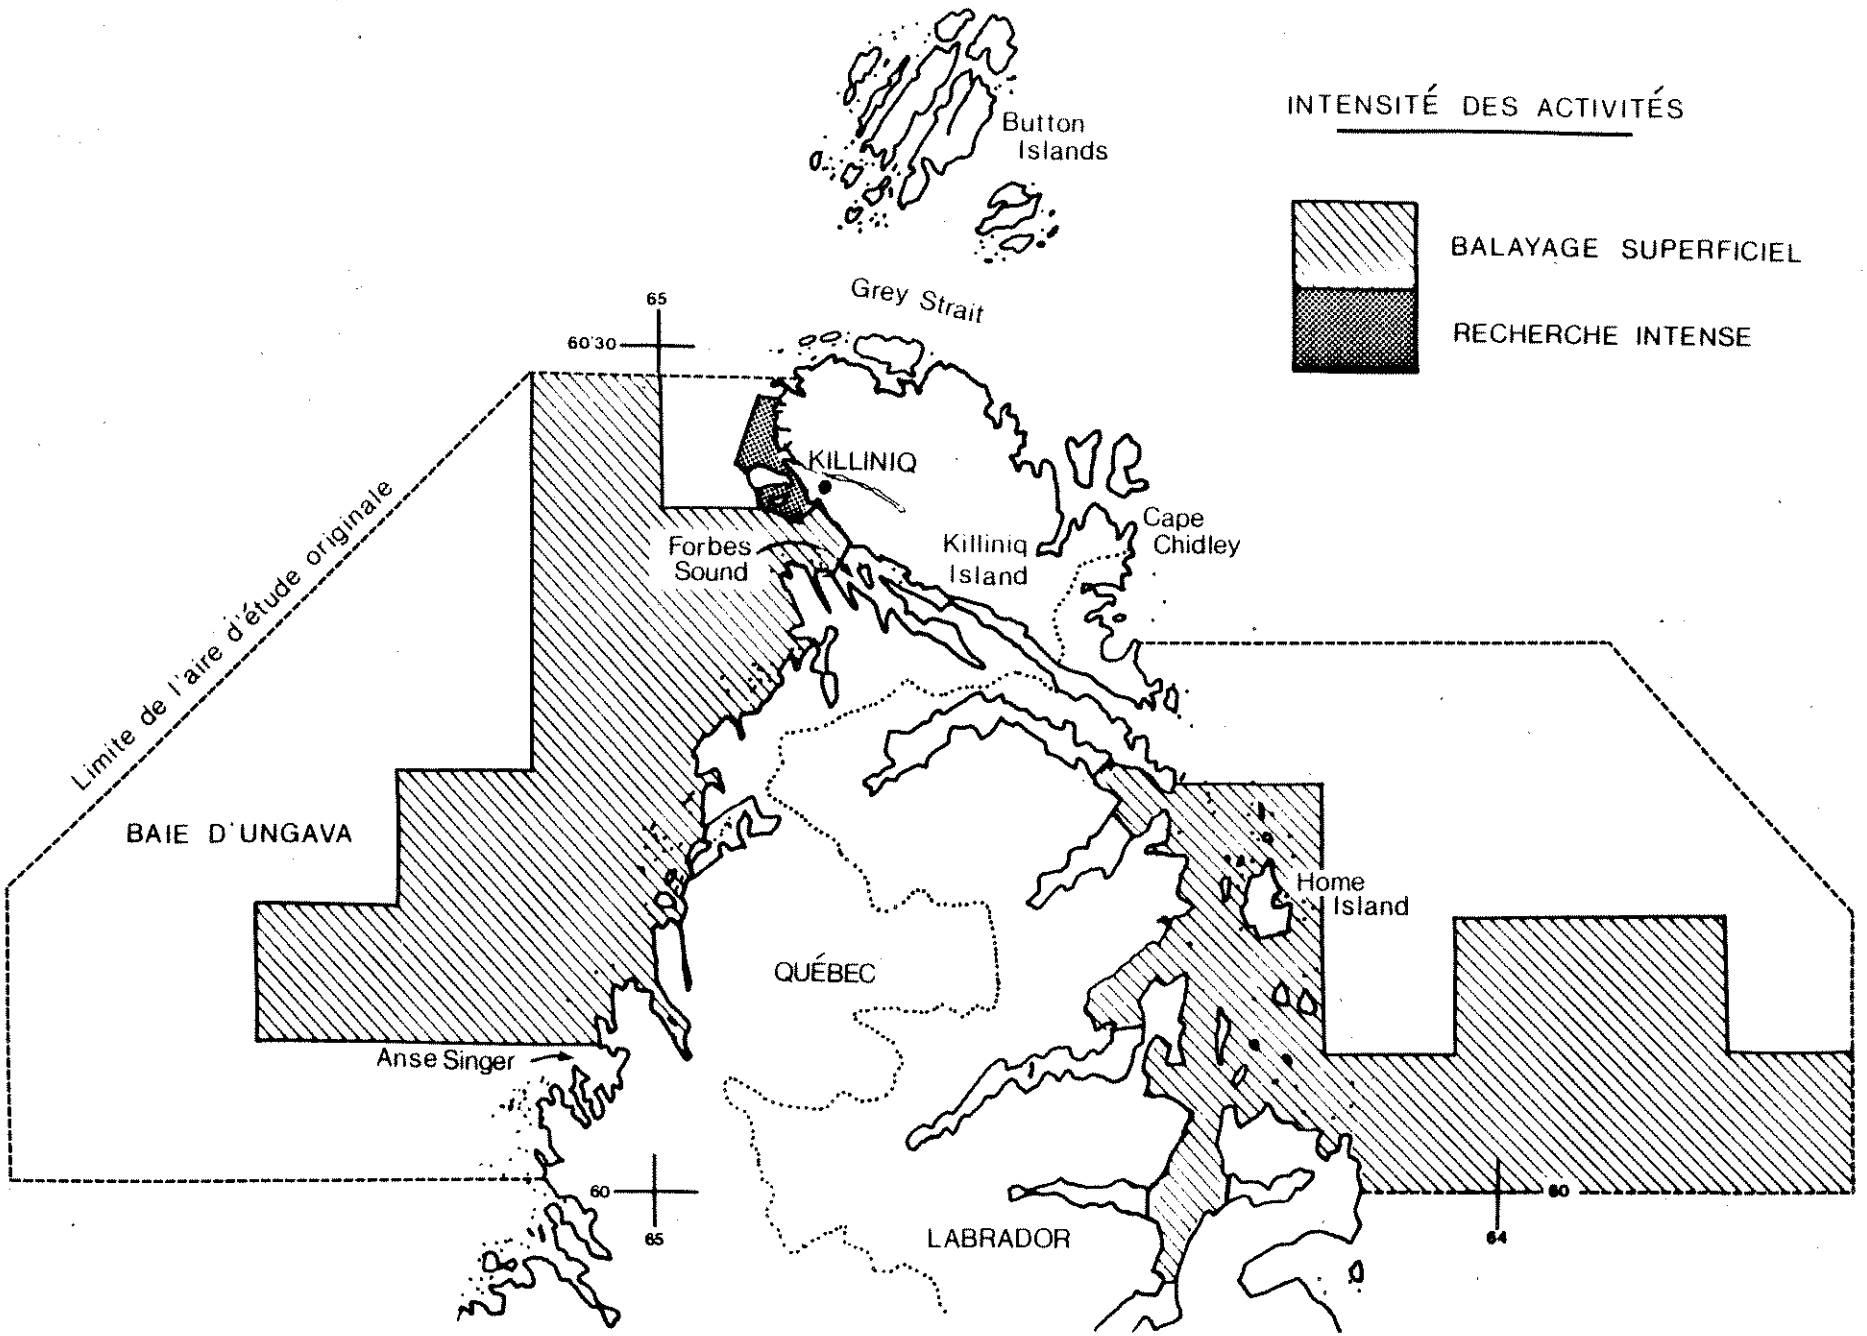

Figure 9: RÉGION DE KILLINIQ ISLAND – INTENSITÉ DES ACTIVITÉS DE LA PHASE I

2. RESOURCES

a) Species and Distributions

Documented catches of fish species by number and weight are summarized in Table 7. The raw catch data from each exploratory effort is presented in Appendix D. Atlantic cod was the only species encountered in commercially interesting concentrations, with a fresh catch of 3,160 fish totaling 13,053 kg (mean 4.13 kg). A further 112 Atlantic cod had been at least partially scavenged, particularly by the Hyas crab.

During this survey, Atlantic cod were not recorded from the northern Labrador coastal waters (figure 10) in exploratory sampling between August 20th and 23rd, however, the total effort directed here was low. Between August 25th and August 30th, sporadic small catches of Atlantic cod were recorded along the Ungava coast south of Killiniq to a point just north of Singer Inlet (figure 10). The majority of Atlantic cod taken were collected from sites close inshore on the west coast of Killiniq Island immediately adjacent to the Killiniq townsite.

The primary gears used in this survey were not effective in catching the numerous smaller marine fish species characteristic of this area (MacLaren Marex 1979, Imaqpik Fisheries 1981, Makivik Corporation unpublished) and the diversity of fish species caught in Phase I was, as expected, quite low (Table 7). Greenland cod (Gadus ogac) were encountered sporadically over the whole area but the total recorded catch amounted to only 13 fish. Five Greenland halibut (Reinhardtius hippoglossoides) were taken between 60 and 85 fathoms just southwest of the immediate Killiniq area. Very little fishing effort could be directed at the water depths normally associated with this species. Six small American plaice (Hippoglossoides platessoides) were taken in one set on the coast of Labrador. Shorthorn sculpins (Myoxocephalus scorpius) were a common catch while polar eelpout (Lycodes turneri) and arctic eelpout (Lycodes reticulatis) were collected occasionally.

TABLE 7 - LIST OF DOCUMENTED FISH SPECIES AND TOTAL CATCHES
KILLINIQ FISHERIES PROJECT, PHASE I

SPECIES	TOTAL #	WEIGHT (Kg)
Atlantic cod (Gadus morhua)	3160	13,053.4
Greenland Halibut (Reinhardtius hippoglossoides)	5	15.15

N.A. = Not available

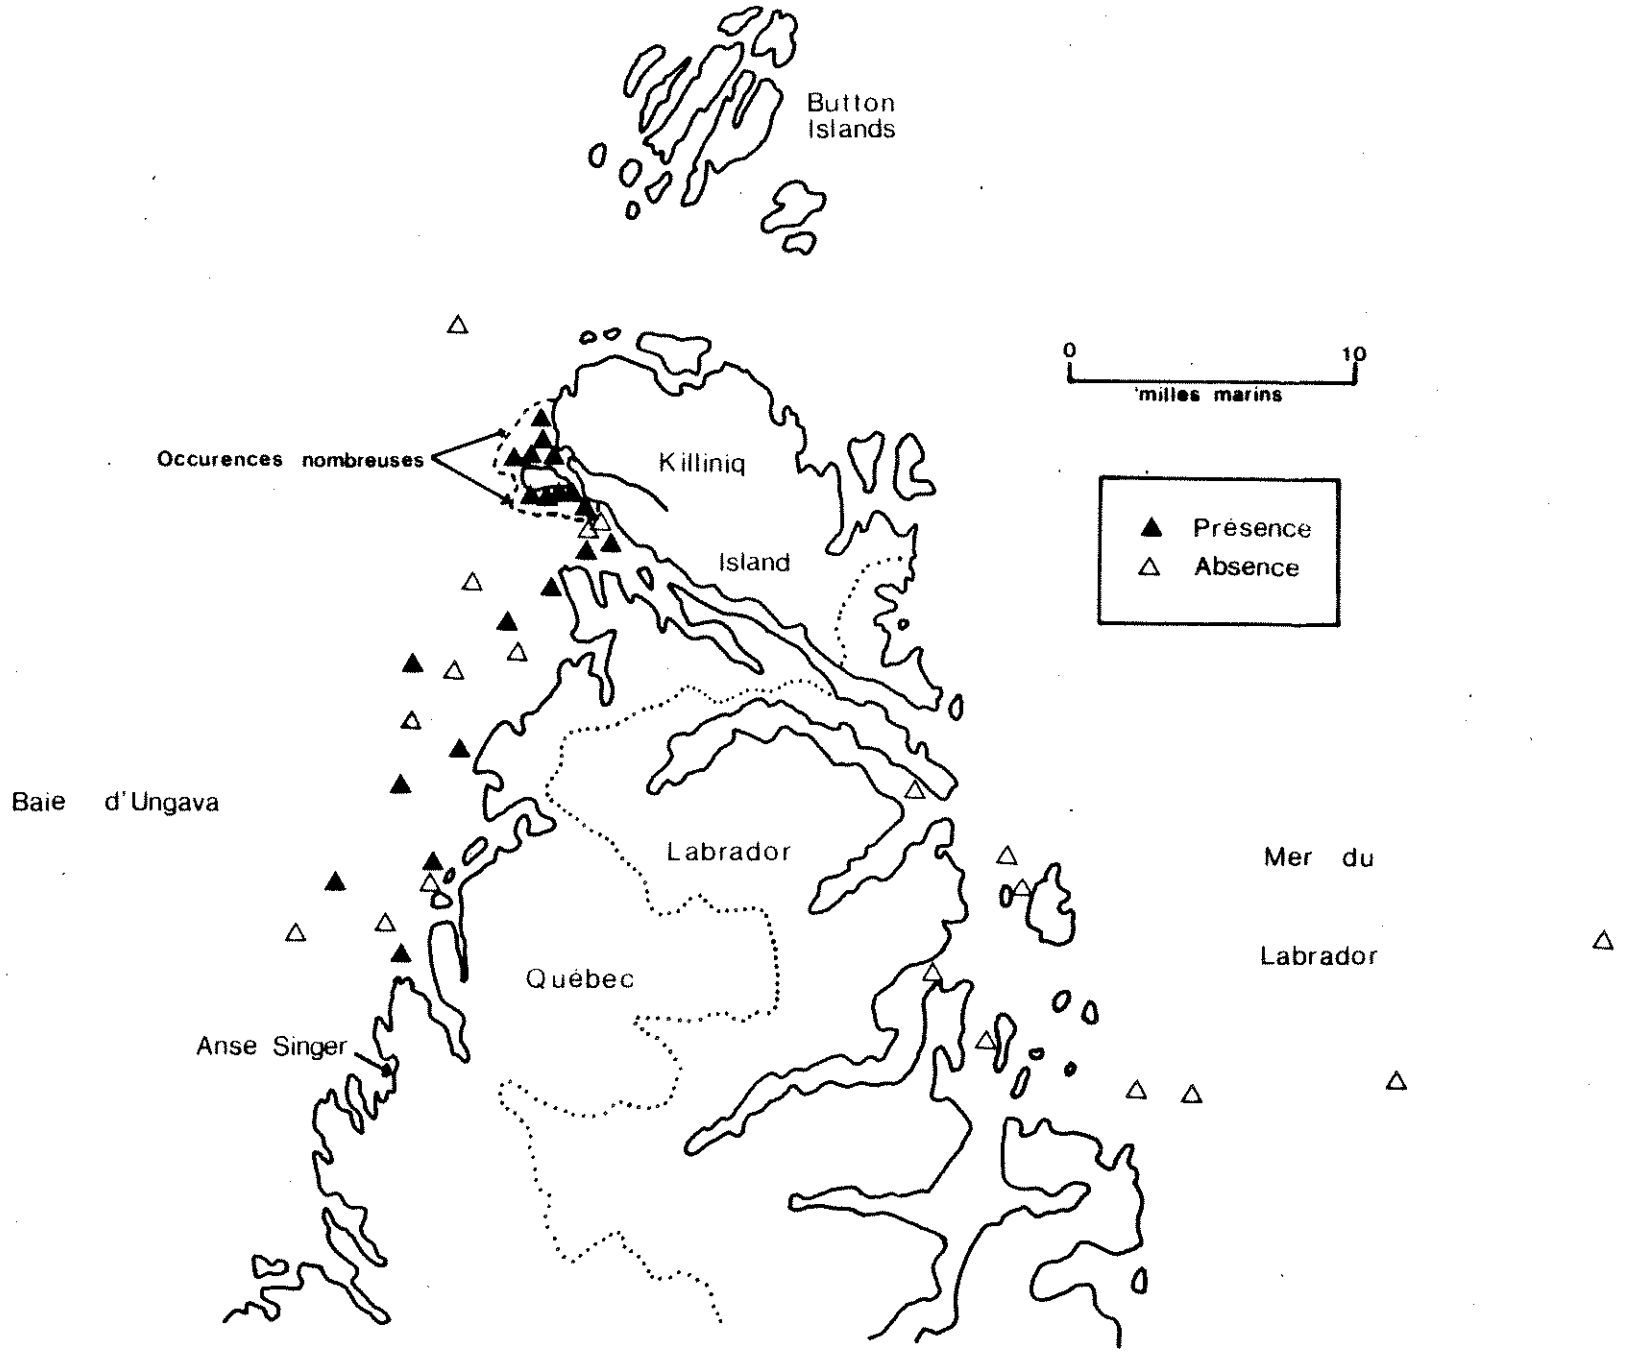

FIGURE 10: OCCURENCE DE MORUE DE L'ATLANTIQUE DANS LES ZONES EXPLORÉES DE LA RÉGION DE KILLINIQ, AOÛT - SEPTEMBRE 1983

A number of seals (approximately 30), primarily harp seals, were caught in cod gillnets during the study. Seals appeared to be numerous in the immediate vicinity of Killiniq. Large seals enlaughed in the nets had to be lifted carefully aboard from the waterline to avoid large tears in the webbing material.

Several invertebrate species deserve mention. While little effort was directed specifically at crab species, a small spider-type crab, probably Hyas coarcticus coarcticus, was omnipresent in gillnet catches. Though fairly small in size, this species was often quite numerous and while the ratio of edible meat was quite low, it was found to be very palatable. Iceland scallops (Chlamys islandicus) were collected from numerous places over the study area in the unusual manner of finding them clamped onto longline hooks and gillnet webbings. Some of these were of commercial size.

The spectacular beds of kelp (mostly Lamimaria sp. and Agarum sp.) which plagued our fishing efforts in many protected inshore areas, both in Ungava Bay and along the Labrador coast, represent in themselves a potentially exploitable resource. In addition to having a wide geographic distribution, these seaplants were found to extend over a wide range of depths from the shore line down to beyond 15 fathoms in some areas.

b) Catch Per Unit of Effort - Atlantic Cod

In Table 8, the area surveyed (figure 9) is divided into three regions and for each of these, the exploratory effort for each of the primary gears and the resultant catch of Atlantic cod per unit of effort is summarized. Only in the immediate vicinity of Killiniq were Atlantic cod found in concentration. Efforts there yielded a respectable overall return of 51.06 Kg of Atlantic cod per net-day. Of the total fresh catch of Atlantic cod during Phase I (13053.4 Kg, Table 7) 98.5% was taken from the immediate Killiniq area. The cod were observed to be distributed primarily

4. kg/net-day

along the inshore slope of a deep (60 to 80 fathoms) channel extending from the western mouth of Burwell Harbour, along the south coast of Jackson Island and north along the west coast of Killiniq Island (figure 8). With strong currents racing just offshore and around the headlands, best fishing was had in the relatively quiet water between these parallel shore currents and the shoreline inside the headlands. Segregated in this way by natural barriers, catch parameters from more specific sites within the immediate Killiniq region can be isolated. The catches of Atlantic cod per unit of effort at six such sites are displayed in figure 11. Munro Harbour was clearly the most productive site with an overall return of 105.61 kg/net-day. Daily catches there were, on several occasions, quite spectacular (Photo 7), ranging up to a maximum of 2830.1 kg from one fleet of four nets. Curiously, catches in Burwell Harbour itself, where most of the successful fishing efforts in the previous cod fishery were directed (R. Buffitt, pers. comm.), were the lightest of all sites in the region, in spite of a considerable effort (52 net-days) directed there during Phase I.

Cod were found over a range of depths from the shoreline to more than 70 fathoms. At Munro Harbour good catches were distributed all over this depth range, but the highest individual catches were taken from less than 30 fathoms. This seemed to be in direct contrast to the other adjacent sites (figure 11) where catches in depths of less than 30 fathoms were light. The planned deployment of the cod trap at the site that had been successfully fished during the previous fishery was cancelled because that cod did not move close enough to the shore at that location during the Phase I field period.

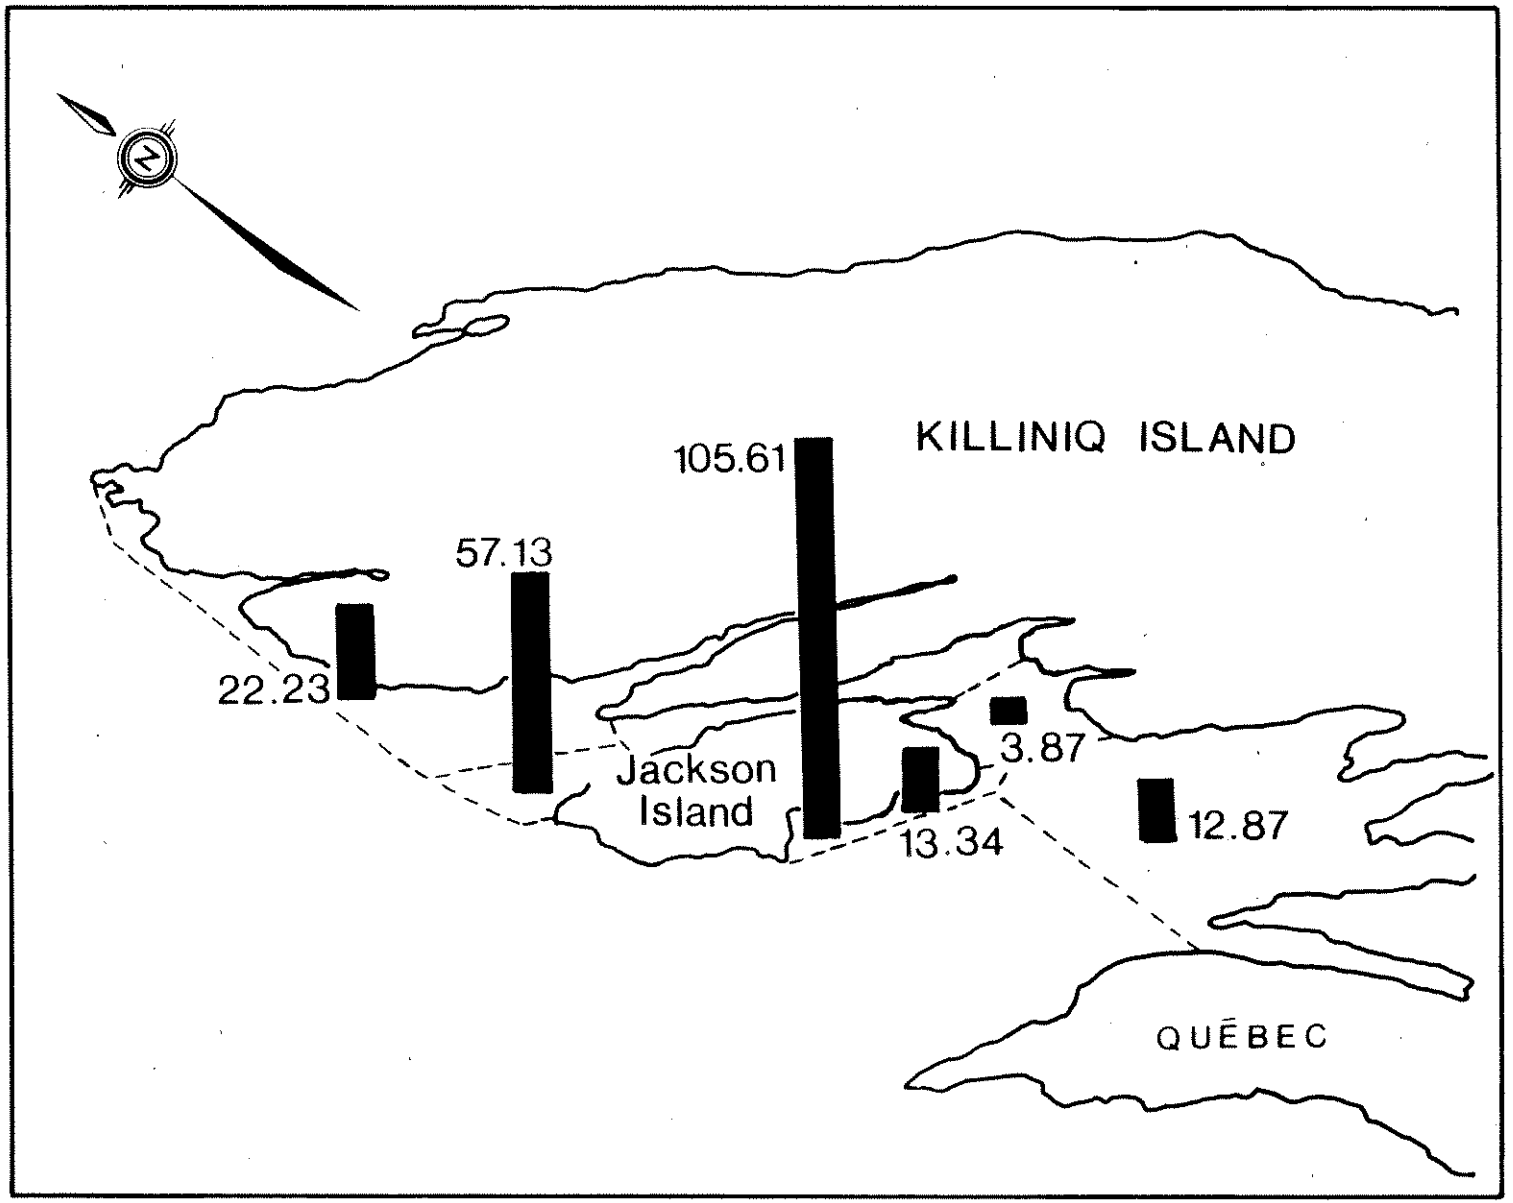

FIGURE 11: PRISE PAR UNITÉ D'EFFORT (kg/jour-filet) DE MORUE DE L'ATLANTIQUE (Gadus morhua) DANS LES ENVIRONS IMMÉDIATS DE KILLINIQ - 30 AOÛT - 15 SEPTEMBRE 1983

3. BIOLOGICAL CHARACTERISTICS OF THE RESOURCE

a) Atlantic Cod

The Atlantic cod encountered during Phase I were of a relatively large and strikingly uniform size. The frequency of individual lengths of cod chosen randomly from the catch is given in figure 12. In this frequency, 48.6% (1519) of all fresh Atlantic cod landed were included. Though they ranged from 43.0 cm to 109 cm, 95% of all fish measured fell between 61.7 cm and 87.9 cm. Males in the catch were of a slightly shorter length on average (73.14 cm, figure 13) than females (75.59 cm) but this difference was statistically significant ($z=6.17$, $p=0.025$). The record of each individual Atlantic cod included in the length frequency distributions may be found in Appendix E.

Detailed autopsies were performed on 633 Atlantic cod and these records are presented in Appendix F. Eight year old fish predominated in the catch (figure 14) with seven and nine year fish making up the bulk of the remainder. The apparent growth rate derived from length at age analysis is high (figure 15). Females were generally slightly larger than males of the same age. In both sexes, the mean asymptotic length, L_∞, (Ricker, 1975) indicated is approximately 105.0 cm.

Females consistantly outnumbered males over the entire range of ages in the catch (figure 16). The final ratio of the sexes was .33:.67 (M:F). With the exception of three small females (43.1 cm, age 3; 43.4 cm, age 4; 44.1 cm, age unknown) which were immature (Stage I), all individuals so examined were observed to be mature and in the recuperation stage (Stage VI).

With few exceptions, the Atlantic cod had been feeding quite heavily prior to capture. The results of analysis of the contents of 75 stomachs is given in Table 9 and Appendix H. . Fish, decapods and amphipods were the most widely recorded food groups. At the species level,

the lantern fish, Myctophum glaciale, occurred most frequently (49.3% of stomachs), followed by an amphipod, Haploops setosa, (38.7%), juvenile Greenland halibut, Reinhardtius hippoglossoides (32.0%) and two decapod shrimp, Lebbeus groenlandicus (25.3%) and Lebbeus polaris (22.7%). In total, invertebrates (93.3%) were more frequently observed than fish prey items (83%), though only marginally. Most fish (86.7%) had been feeding on more than one species (average 3.33 species/stomach). The numbers of fish feeding exclusively on either fish or invertebrates were quite low at 6.7% and 18.7% respectively. Fulton's condition factors, K, (Ricker, 1975) were an average of 0.939 for all fish (Table 10), with an insignificant difference between the sexes.

A representative collection of parasitic organisms was retained in 5% glycerine alcohol from 41 Atlantic cod during the study for identification by Dr. Mark Curtis at the Institute of Parasitology in Ste-Anne-de-Bellevue. Out of these samples, three species, two nematods (Anisakis sp. and Thynnascaris adunca) and one cestode (Abothrium gadi) were identified (Curtis, 1984, Appendix I). Abothrium gadi is found in the intestines of cod and related species and is of no known pathogenic importance to the fish nor does it affect human consumers (Ibid.).

Thynnascaris and Anisakis are usually found in the liver of infected fish, although both may migrate into the flesh after death. The ingestion of either parasite species in raw or pickled fish may cause the condition anisakiasis in humans. However, serious complications to this condition are unusual (Ibid.).

No codworm (Phocanema decipiens) were identified among retained parasite specimens or observed during the study.

b) Other Species

With very low abundances by comparison, little biological data is available from commercial species other than Atlantic cod. This data is presented in Appendix G.

The average round weight of all Greenland cod recorded (13) was 1.93 kg. Autopsies on eight fish revealed 6 females (l = 531.0 mm, wt = 1.47 kg) and two males (490 mm, 1.20 kg; 580 mm, 2.80 kg). Of these fish, six were aged and all were 9+ or 10+ years old. Of five Greenland halibut caught, four were females (l = 652.2 mm, wt = 2.96 kg) and one male (686 mm, 3.30 kg). The ages of some fish could not be refined to one particular year-class and so ranged from 9 or 10 years to 14+ years.

The six American plaice (4 male:2 female) caught on the Labrador coast had an average total length of 385 mm (range 330 mm - 470 mm) and an average weight of 0.45 kg (range 0.25 kg - 0.70 kg). These fish were not aged.

4. PRODUCTION

It is estimated that 10% (1305 Kg) of the fresh Atlantic cod caught in Phase I were consumed locally, stored frozen or otherwise not produced as a heavy salt-cured product (Photo 8). Most fish were split and

salted onboard the "Silver Condor" (Photo 5 and 9) and carried in this manner to Lourdes-de-Blanc-Sablon, Québec, at the completion of the field season. There, it was sold to the Canadian Saltfish Corporation whose inspectors divided the product into standardized commercial grades (Photo 10). In size, over 90% of the produce was graded 'large' and 'extra large'. Total product weight at the time of sale was 3337 Kg. Of this, 45.5% (1515 Kg) was graded "choice" and 54.6% (1822 Kg) was "standard". Prices received for these grades ranged from $.60 to $1.43 per kilogram, depending on the size group. Revenues from the sale of the produce totalled $3390. Fish graded as "standard" were found to be incompletely cured. Two reasons for this have been put forward. Normally, the curing period for this product is 21 days while most of our catches had been taken within 21 days of the time of sale; the most recent catches were on salt for only 13 days. This situation was aggravated by the type of salt we chose (Fishery # 4) which apparently did not dissolve as readily as some other salts which are available. Nevertheless, the quality of the raw product and its treatment were otherwise judged to be excellent. Table 11 presents the ratios of various product states to round, fresh weight as recorded during Phase I.

E. DISCUSSION

1. GENERAL RESULTS

The physical characteristics of the Killiniq area presented a challenging set of conditions in which to fish with static fishing gears. Sea ice and then set and tidal currents precluded a rigorous exploration effort in large sections of the planned study area. Nevertheless, it was possible to carry out all of the essential elements of the planned program and the results are quite encouraging.

The Atlantic cod resource adjacent to Killiniq was re-located and knowledge of its geographic distribution, geological characteristics and abundance has been expanded. Though the known quantity of this resource is still relatively small, catch rates were of commercial levels and the fish and their products were of a very high quality. The operational experience gained early in the program resulted in a greatly increased efficiency of fishing effort over the course of the study. Further, the Inuit of Killiniq who have been involved directly in the project have shown an active interest and considerable ambition and aptitude in each of their roles.

On this basis, the completion of developmental studies toward re-establishing a commerical marine fishery in this region is warranted. The experience of working in the area during Phase I has identified the operational and logistical problems to be faced to the point where future studies may approach them more directly, and further improvements should result. Further exploratory fishing can now be focused on those sites within the operational radius of Killiniq which are most likely to be productive. A number of such sites have already been tentitively identified, particularly on the east side of Killiniq Island.

2. OPERATIONS

From an operational standpoint, the Killiniq area presents a challenging set of physical conditions in which to operate an inshore fishery using primarily static fishing gears. Without the benefit of any documented experience in such activities, our initial attempts at deploying static gears, in Ungava Bay in particular, met with problems. Though the nets and longlines used were well constructed and the vessels and crews well equipped for their operation, strong currents and lingering sea ice took its toll on many of our initial efforts. Fishing on the northern-most coast of Labrador would appear to be well within the capabilities of a small well-equipped multipurpose vessel down to the range of 12.2 meters in length, provided that the area is free of sea ice. To have sea ice lingering over these waters as late as in the 1983 season was quite unusual, but the adaptation of static gears to cope with even minor concentrations of drifting ice is, in any event, an operational problem for which there may be no immediate practical solution.

Conditions are most severe in Ungava Bay, where the major operational factors to be faced are the strong set and tidal currents. As designed, gears on hand during Phase I could only be effectively deployed over a small part of the study area in Ungava Bay. Certain modifications in the gears and in particular in the method of their deployment were made in the field, and these changes resulted in a marked improvement in the efficiency of our efforts over the course of the Phase I program. The number of net buoys used per set was increased to two in some cases to overcome tidal pressure on haulup lines, but the greatest improvement resulted from learning to anticipate where currents would be severe. Additional experience in the area and experimentation with gears and techniques used in similar situations elsewhere will undoubtedly result in a further improvement. It is recommended that future developmental studies incorporate a specific program to identify and test these alternatives under the guidance of specialists in that field. The evolution of efficient and cost-effective fishing methods will be a critical factor in the successful development of a commercial fishery in the Killiniq area.

The poor results from the fishing efforts with longlines during Phase I were disappointing. Longlines offer several important advantages over gillnets; they yield a better quality raw product and they pose less of a problem if they go adrift. The only other known attempt at using longlines in Ungava Bay met with similar results (Grainger and Dunbar, unpublished), although one quite successful trawl was set overnight on the bank east of Home Island, Labrador, in August, 1965 (R. Buffitt, pers. comm.). Further attempts should be made to investigate this gear's effectiveness, particularily in the quest for Greenland halibut in the deeper waters of the Labrador Bank, east and south of Killiniq (figure 9). In these attempts, emphasis should be placed on the effectiveness of local sources of bait or artifical baits thus avoiding the logistical difficulties of having to make the more traditional longline baits, such as squid or herring, available in the north.

Based on the experiences of Phase I, several other suggestions concerning vessels and gears can be stated. There will continue to be a continuing role for a multipurpose vessel(s) in the range of 12.2 meters in both the development and operation of an inshore fishery in this region. The extended operational radius and greater weather capability that these vessels offer over smaller craft is obviously an attractive feature. Nevertheless, all of the abundant fisheries resources so far identified were found quite close to the base at Killiniq, and were well within the range of a smaller vessel. These resources may be harvested quite efficiently with a trap boat suitably equipped for tending gillnets. The advantages of this approach are that the trap boats are relatively inexpensive to acquire and operate, and though they are of a heavier design, they are similar to the larger freighter canoes widely used by Inuit in the area. Trap boats are widely used in similar situations in other areas and should be considered in this case. With minimal modification, they are suited to the operation of a cod trap, gillnets, longlines, and both hand and automatic jigging gear. The automatic jigging machine remains untested after Phase I but may be quite effective for harvesting cod near Killiniq, particularly if, as was the case in Phase I, large numbers of cod remain in deeper waters beyond the reach of a shore-based cod trap fishery.

3. RESOURCES

a) Atlantic Cod

From the standpoint of commercializable fisheries resources, the results of our survey efforts were encouraging. Though no fish were taken from Labrador, the effort was minimal and, based on previous accounts (Wakeham, 1898; Bernier, 1910), it is likely that species such as Atlantic cod and Greenland halibut would be found in a more complete survey over a longer season. The extent to which Atlantic cod move into Ungava Bay south of Killiniq remains unclear. The sporadic small catches observed there during Phase I are somewhat inconclusive as a result of the difficulty of sampling those waters during this part of the survey. Because of the strong currents offshore, any sizable concentrations of Atlantic cod migrating into northeastern Ungava Bay may be restricted to the nearshore waters. In four research surveys for shrimp species in the offshore areas of Ungava Bay and Hudson Strait between 1978 and 1980, only three Atlantic cod were reported from a total of 283 bottom trawls with small mesh nets. (Maclaren Marex, 1979; Makivik Corporation, unpublished; Imaqpik Fisheries, Unpublished data; Imaqpik Fisheries, 1981).

On the other hand, the concentration of Atlantic cod located close to Killiniq Island is clearly of commercial potential. Overall catch per unit of effort was quite high and in fact was clearly increasing as the study progressed, though this was, at least in part, due to an increase in operational efficiency. The area over which this resource has been delineated is, so far, quite small, as only that section of coast from Burwell Harbour to the northwest tip of Killiniq Island was intensively surveyed. On the north and east coasts of the island, quite a number of likely sites remain untried, several of which, such as Harvey Bay, McLellan Strait (Bernier, 1910) and O'Brien Harbour (Wakeham, 1898) are known to have been fished for cod in the early years of this century.

The present study sheds little light on the question of the seasonal availability of Atlantic cod within the area. Fish may have been present in the area for some time before they were located in late August,

1983, although if this were the case, they would have to have been lingering under a cover of ice. When sampling ceased on September 15, cod were abundant. Various authors (Wakeham, 1898; Grenfell, 1909; Bernier, 1910; Grainger and Dunbar, unpublished; Evans, 1958) present arrival dates ranging from mid-July to late August. Similarly, the cod have been reported to leave the area anywhere between mid-September and mid-October. All these authors may be correct, as one major controlling factor in the cod's inshore summer feeding migration seems to be water temperature (Templeman, 1966), which is quite variable annually. Wakeham (1898) does say that there was a consistent delay of about one week between the arrival of Atlantic cod at O'Brien Harbour, on the east coast of Killiniq Island, and at Killiniq. He relates that good fishing also ended about two weeks earlier at Killiniq.

The fish themselves were uniformly large and in excellent physical condition. Results would indicate that their presence in such inshore areas is related to feeding activity, a widely documented seasonal phenomenon in other areas (Liem and Scott, 1966). These fish represent a superior raw material for a range of potential products. While these characteristics are encouraging from a commercial standpoint, they raise several important biological questions. Prior to the present study, the only complete biological account of Atlantic cod taken at Killiniq was done by E.H. Grainger and M.J. Dunbar (unpublished) based on samples collected between 1947 and 1950. Their fish were jigged from the Fisheries Research Board of Canada's vessel the "M.V. Calanus" on visits to Killiniq in the summer and early fall during studies of the biological and physical oceanography of the region. Comparisons of a wide range of descriptive parameters highlight some striking differences between the two samples. The fish in the 1983 sample were much larger (figure 17, Table 12), to the point where the average length of the catch in 1983 falls outside the observed range in the earlier sample. It must be pointed out that Grainger and Dunbar's fish are the summed catch from four years. Also, the earlier sample was jigged while the present sample was collected with gillnets, and these gears are differentially selective. Almost all of the fish represented in the length frequency of the 1983 catch were taken from a mixture of

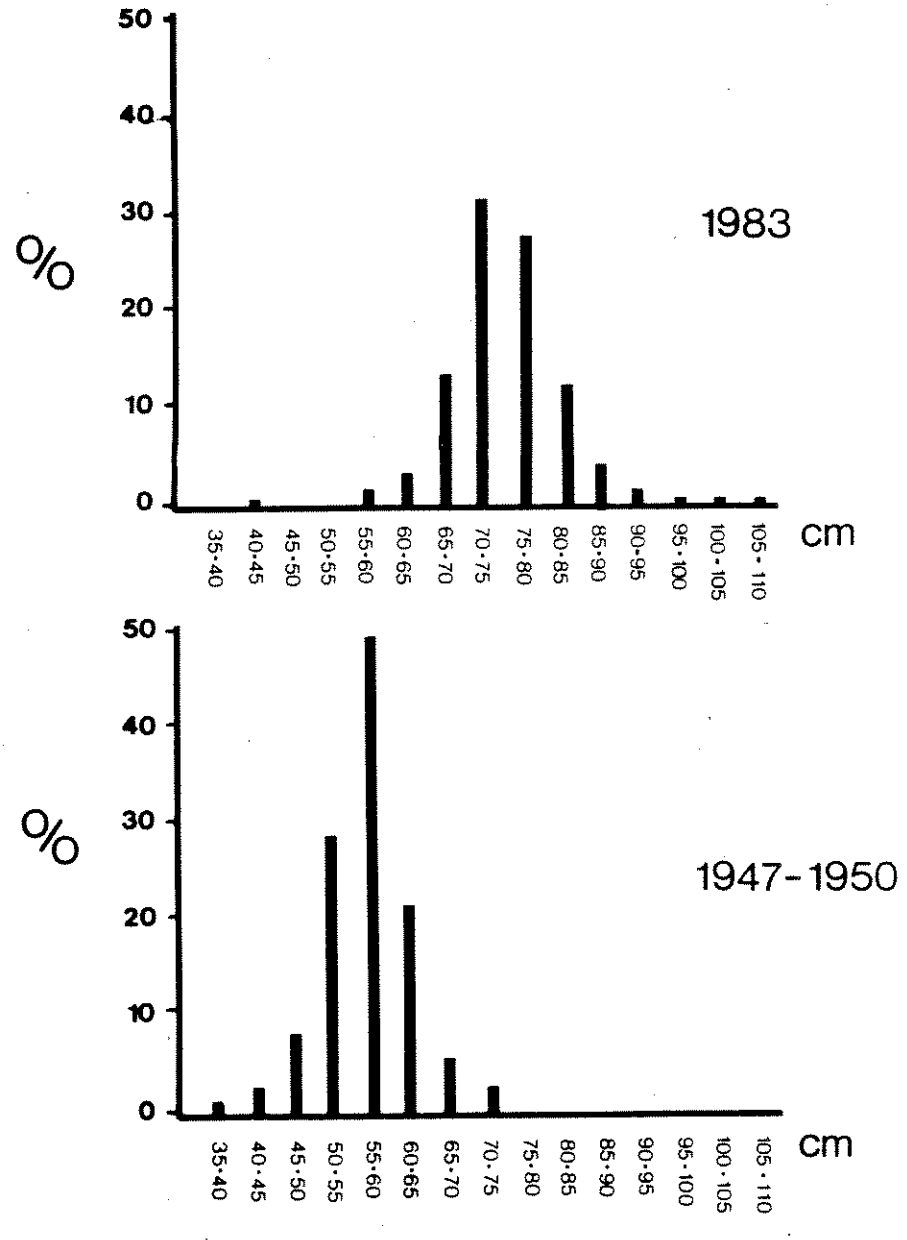

FIGURE 17: RÉPARTITION DE LA FRÉQUENCE RELATIVE DES LONGUEURS TOTALES – MORUE DE L'ATLANTIQUE PROVENANT DE LA RÉGION DE KILLINIQ – 1947–1950 (Grainger & Dunbar, inédit) et 1983 (présent rapport)

TABLE 12 - COMPARISON OF SOME DESCRIPTIVE PARAMETERS IN SAMPLES OF ATLANTIC COD TAKEN FROM KILLINIQ IN 1947-1950 (Grainger and Dunbar, unpublished) and 1983 (this report).

	SAMPLING PERIOD	
	1947-50	1983
N	666	1519
Length:		
Average	56.4 cm	74.8 cm
Stand. Dev.	N.A.	6.55 cm

L_∞ (estimated)	65.0 cm	105.0 cm
M:F	36.9%:63.1%	33.0%:67.0%

5½", 6" and 7" meshes. Using the cod gillnet selectivity curves in Clay (1981), it is possible that length classes under 65.0 cm could have been significantly under-selected. It seems unlikely though that such discrepancies could be attributed solely to that source. Length at age also differs dramatically between the two samples (Table 13). Mean asymptotic length, L_∞ (Ricker, 1975), is estimated to be 65.0 cm and 105.0 cm for 1947-50 and 1983 respectively. The possibility always exists for a discrepancy of one year in the interpretation of age from the otolith by different researchers. However, in this case, the discrepancy would have to be at least several years, which seems unlikely.

Grainger and Dunbar (unpublished) recorded a much greater diversity of prey species in the stomachs from 1947 to 1950, albeit from a much larger sample (over 1000). All of the more numerous food species observed in 1983 (Table 9) were recorded in the previous study although the myctophid, Myctophum glaciale, was only of minor importance in 1947-50.

Based on average vertebral counts, Grainger and Dunbar were able to show, as did Vladykov (1933) before them, a clear affinity between the fish in their sample and Atlantic cod from the Labrador coast and Newfoundland. No biological accounts of the Atlantic cod upon which the commercial fishery of the 1960's and early 1970's were based has been located, however, the recollections of some of those involved in these fisheries seem to generally fall in line with the account of Grainger and Dunbar (Raymond Buffitt, Economic Development Officer at Killiniq, 1961 to 1965; Neil Greig, Plant Manager, 1971-1972; personal communications). During these fisheries, cod were harvested primarily inside Burwell Harbour, in 20 fathoms of water or less. Conversely, in 1983, catches in the Harbour were light and sporadic; the cod only moved into shallower waters (less than 30 fathoms) in large numbers at Munro Harbour (Figure 8). As late as 1977, three small Atlantic cod jigged in Burwell Harbour (Maclaren Atlantic Ltd, 1978) were of individual lengths at ages (male, 42.7 cm, age 8; male, 47.5 cm, age 6; female, 46.8 cm, age 5) which seem typical only of those documented by Grainger and Dunbar (Table 13) from the same site.

Two explanations for the striking dissimilarity between the two accounts can be put forward. The first is that the 1983 cod may be of West Greenland origin, their occurrence at Killiniq possibly being related to a change in environmental conditions in the general area. The alternative is that the individual growth rates of Atlantic cod from the local area have increased substantially since 1950. Both explanations are feasible in the sense that there have been similar phenomenon documented in other areas. Unfortunately, meristic samples from the 1983 catch which would have indicated an affinity with either the West Greenland or Labrador stocks were not collected.

The apparent growth rate of the fish in the 1983 sample is quite similar to fish from the West Greenland stock (Meyer, 1973; Simachyova, 1975). A warming of the climate, and therefore sea temperatures, of the northwestern Atlantic between 1880-90 and 1945, altered the distribution of Atlantic cod off West Greenland, much to the benefit of the cod fishery there (Cushing, 1978). In eastern Canadian waters, the present trend in sea temperatures is uncertain following a prominent peak about 1950, how-

ever, the long-term pattern seems to be downward (Dunbar, 1982). The relationship between such changes in sea temperatures in Canadian waters and any corresponding changes in fish distributions has not yet been determined. At the present time, however, there is some evidence in support of the theory that there has been an increase in the rate of growth of local cod. Table 14 presents what length at age data is available fron NAFO division 2G and/or the Killiniq area itself from fish collected over the period between the two samples. Age 7 was chosen as the strongest common age class. Between 1947-50 and the mid-1960's a slight increase in growth is indicated. This parallels the results of May (1966) who analysed NAFO DIV. 2G inshore data over the same period and attributed the change to decreased stock densities due to greatly increased fishing off southern Labrador. The further increases recorded in 1979 and in 1983 are of a greater magnitude. Cod growth rates have been known to change substantially in response to external influences such as food availability (Kohler, 1964) stock densities (May, 1966; Wells, 1983), prey size (Lilly, 1980) and temperature (Taylor, 1958; Herman and Hansen, 1965; May et al, 1965). An upward shift in the growth rate of cod on the Flemish Cap southeast of Newfoundland over the last thirty years in which prey size (Lilly, 1980) and stock density (Wells, 1983) may have been contributing factors, has been of an even greater magnitude than the discrepancy between the two samples available from Killiniq.

Aside from the intriguing ecological implications, the resolution of this question is of direct importance to the re-development of the Killiniq fishery. If indeed the present cod resource is not of Labrador origin, its continuing availability in the short and long term becomes a matter of speculation. On the other hand, if they are Labrador cod growing at an increased rate, they should be available to a fishery on a more dependable basis. Meristic studies and a tagging program must be priority items on the agenda for Phase II.

TABLE 14 - MEAN TOTAL LENGTH AT AGE 7,
NAFO DIVISION 2G AND KILLINIQ, 1947 to 1983.

b) Other Species

The low catches of species other than Atlantic cod must be interpreted while considering the areas adequately sampled and the gears used during the survey. This is particularly true of Greenland halibut. Little effort was directed during Phase I over water depths with which this species is normally associated (Lear and Pitt, 1971). Good catches of sizable Greenland halibut are reported from an area 25 nautical miles WSW of Killiniq (MacLaren Marex Inc., 1978; Imaqpik Fisheries Inc., 1981) in August of both 1978 and 1979, where water depths ranged from 100 to 200 fathoms. Given that this area also features strong currents (Imaqpik Fisheries Inc., 1981), longlines or other static gears may be difficult to use effectively there. On the Labrador bank to the east of Killiniq Island, however, further exploratory fishing for Greenland halibut should be attempted.

Beds of Iceland scallops of commercial quality and quantity have been delineated as far north as Nain, Labrador (Barney, et al, 1982). In that survey, some scallops were found over most of the areas sampled but concentrations tended to be close to shore and in narrow passages. The inclusion of exploratory sampling with proper scallop dredges in future studies in both Ungava Bay and northern Labrador, is recommended. While the Hyas crab seemed to be generally abundant in the study area, it would seem that the small individual size and low edible weight per individual would remove it from consideration as a potentially commercial species. The occurrence of larger, more marketable species such as the snow crab (Chionoecetes opilio) remains virtually unassessed in these areas, although no significant catches have been reported from shrimp (Pandalus sp.) research efforts offshore. Exploration for marketable crabs should continue although, given the space that standard crab pots require on the small vessels presently used, these efforts may be of an opportunistic nature.

Several other potentially commercializable resources should be mentioned. Greenland shark (Somniosus microcephalus) are well known to residents of Killiniq, having been a freqent by-catch in the seal fishery in late fall (R. Buffitt, pers. comm.). There have been sporadic fisheries

for this shark in some northern regions (Dunbar, 1952), the oil of the enormous liver and, to a certain extent, the leather, being the primary products. The current market for shark products should be investigated. The apparently abundant beds of seaplants encountered in Phase I must be considered a potentially exploitable resource, although they were more often considered a nuisance which frustrated efficient gillnetting. Future surveys should at least collect specimens to identify species and continue to note its distribution.

4. PHASE II

Phase I of this study has provided much information about the resources of the Killiniq area, and has illuminated many of the operational realities to be faced there. Phase II can and should now address those problems directly and build on the results of Phase I.

The following recommendations are put forward to guide the development and realization of the Phase II program.

1. The involvement of Inuit fishermen and workers in the field studies should be increased, and the number of southern personnel reduced correspondingly. Two experienced southern fishermen could provide what supervision and training would be necessary to complete the major part of the field program recommended with an Inuit workforce. The familarization of these local people with the techniques and skills that they would require to operate a bona-fide fishery can only be accomplished properly if their involvement is of a very real nature.

2. An experimental fishery should be established at Killiniq based on the Atlantic cod resource surveyed during Phase I. The goal of the operation should be to test the ability of that resource to sustain a fishing operation over the full available season in a realistic manner. It would also provide the framework into

which several specialized studies may be integrated. All fishing and processing of fish should be done by Inuit with the technical support of the southern fishermen. Primary gears used should be a cod trap and/or commercial gillnets, however the latitude to incorporate other still untested gears when their efficiency becomes clear must be retained. The effectiveness of well-equipped trap boats (in the range of 9 meters) should be tested in this fishery. Cod should be split and heavy-salted. Once cured, a portion of the product should be further processed into dry salt fillets on an experimental basis. Fish products should be sold, at the end of the field studies to document market response, and the monies realized returned to the project specifically to offset production costs.

3. Exploratory fishing in adjacent areas for Atlantic cod and other species should continue, albeit, in deference to the physical realities of the area, within a more flexible sampling program. One small, well-equipped longliner, preferably in the range of 12 meters, should be available to undertake the exploratory fishing during the earlier part of the season and support the experimental fishery in the latter weeks when weather may become a factor inhibiting the effectiveness of the trap boats. Areas which should be focused upon are the north-east and east coasts of Killiniq Island, the offshore bank east and south of Killiniq Island and, subject to gear modification, sites along the coast of Ungava Bay south-west of Killiniq. Primary gears should be commercial and experimental cod nets although further attempts at longlining using local bait sources should be made particularly offshore on the Labrador side. Test fishing with purpose-built scallop gears seems warranted in Phase I.

4. A special program to observe, modify and test fishing gears and methods to better adapt them to the local conditions, is recommended. An appropriate gear specialist should be at the site for a period during the peak of the fishery to maximize the effect of this program.

5. Arrangements should be made to have a production specialist present at the site to observe and document first hand the raw resource and the logistical realities of the area. The subsequent report of this specialist could identify realistic options for present and future product forms, as well as outline the required facilities and the logistical considerations to be taken into account in each case.

6. Standard biological sampling should continue on commercial species, though in the case of the experimental fishery, disruption of the operation should be kept to a minimum. Stress must be placed during Phase II on the determination of the stock affinity of the Atlantic cod resource and collection of detailed growth parameters of individual fish.

2. Acknowledgements

The design, implementation and accomplishment of the present program has been the result of the cummulative efforts of a large number of people. Those who have been most heavily involved on a continuing basis in all aspects of the study have been identified as core staff (section G.1). While the authors of this report remain responsible for the disemination of information and results of the program, the input of the other core staff, in particular, that of Fritz Axelsen to the realization of the study must be clearly recognized.

The contributions of the following groups and individuals to the success of our efforts is gratefully acknowledged:

Jean Garon, Minister de l'Agriculture, des Pêcheries et de l'Alimentation du Québec, for his support of this program.

The Government of the Northwest Territories for the use of existing facilities at Killiniq, and in particular, Mr. Ralph Brown, assistant to the Regional Director, for facilitating those arrangements

The 1983 staff of "VAW" Killiniq Coast Guard Radio Station, Marc Ruest, Manager, for numerous considerations before, during, and after the field season.

The air crew of the M.O.T. Bell 212 helicopter, Bob Peltier, Captain, for the transport of personnel and materials to and from Killiniq early in the field season.

Transport Canada, Fleet Operational Services and the crew of "C.G.S. Des Groseillers" for the safe delivery of materials to and from the site.

Leonard Dorion, Receiving Officer, at the M.O.T. Coast Guard Base at Québec for his cheerful assistance in difficult circumstances.

APPENDIX A - Photographs

The following collection of photographs depict many of the essential elements of the Killiniq Fisheries Project, Phase I.

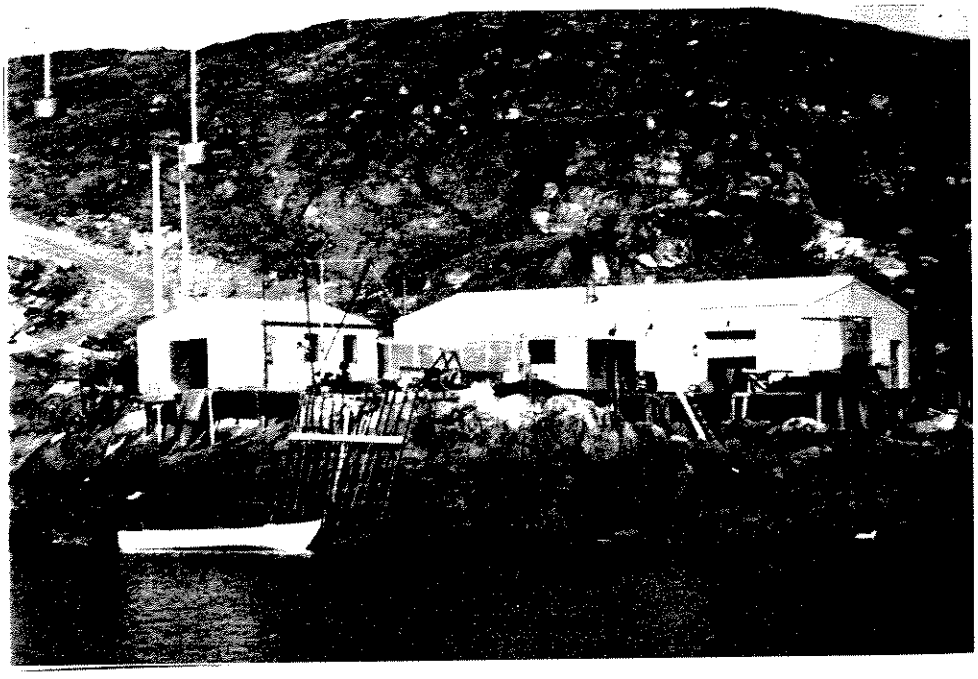

Photo 1. The Fish Plant at Killiniq.

The plant site assumed its present form in 1968 with the construction of the processing and storage building (large structure on the right). Other facilities include a small freezer (center - foreground) and the old plant building (left). A small power house is not visible behind the old plant building. All these facilities are connected by a plank deck which extends out over the sheer stone face of the point. This natural wharf can accommodate vessels up to 25 meters in length whenever the tide is at least ½ full. A small gasoline-powered hoist sits on the edge of the wharf. The road to the left runs to the townsite approximately 1/4 miles distant.

All these facilities are in reasonably good condition with the exception of the freezer building which requires a complete mechanical and structural overhaul.

The vessel in the foreground is the trap boat used by the project during Phase I.

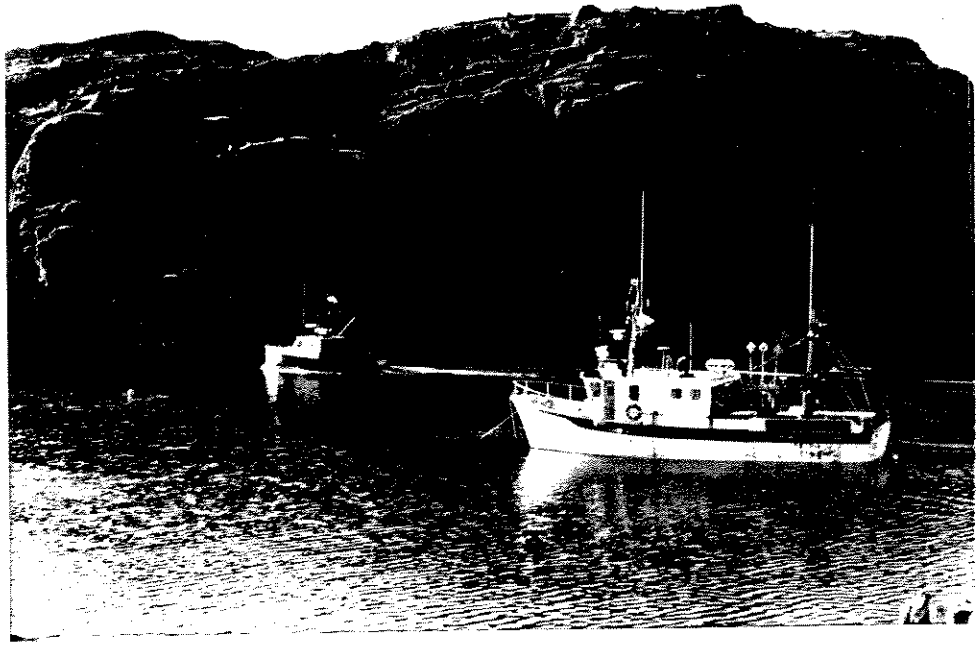

Photo 2. Two chartered fishing vessels in the harbour at Killiniq

The "F.V. Silver Condor" (at anchor in the foreground) is a 16.7 meter stern trawler. The "F.V. Cindy Roger" (departing to the left) is a 12.2 meter longliner/gillnetter. Details of both of these vessels are given in section C.2.b.i (Table 1) of this report.

This view is from the deck at the fish plant (Photo 1) with Jackson Island in the background. This inside harbour at Killiniq is ideal for such vessels, being completely protected and retaining sufficient water (6 fathoms) at low tide. Note the tide marks on the shore opposite.

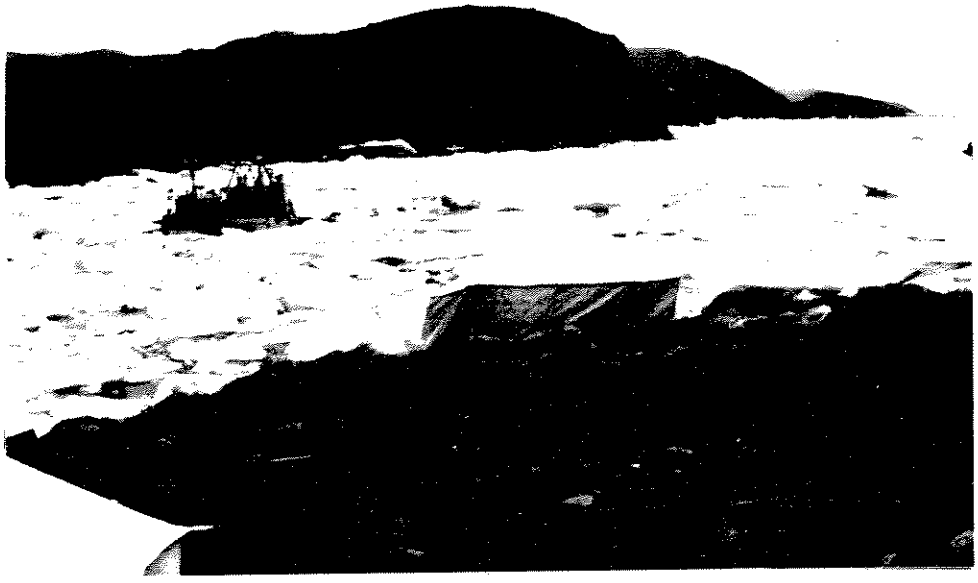

Photo 3. Project vessels trapped by ice in Fox Channel, Aug. 16th, 1983.

Fox Channel separates most of Jackson Island (background) from Killiniq Island (Figure 8). A sill, which is only temporarily covered at high tide, separates Fox Channel from the plant harbour (Photo 2).

The vessels became trapped when the ice pack in Ungava Bay (extreme right, background) moved against the coast between August 14th and 19th. While there was no danger to the vessels, they could not be moved for a number of days.

The tents in the foreground are the type widely used by the Inuit.

Photo 4. Staff buoy and trailing net buoy (60" dia) in Ungava Bay

Though not at their extreme in this particular case, tidal and set currents in Ungava Bay frequently submerged such floatation gears.

This location is approximately five miles due west of Killiniq Island (background) in Ungava Bay.

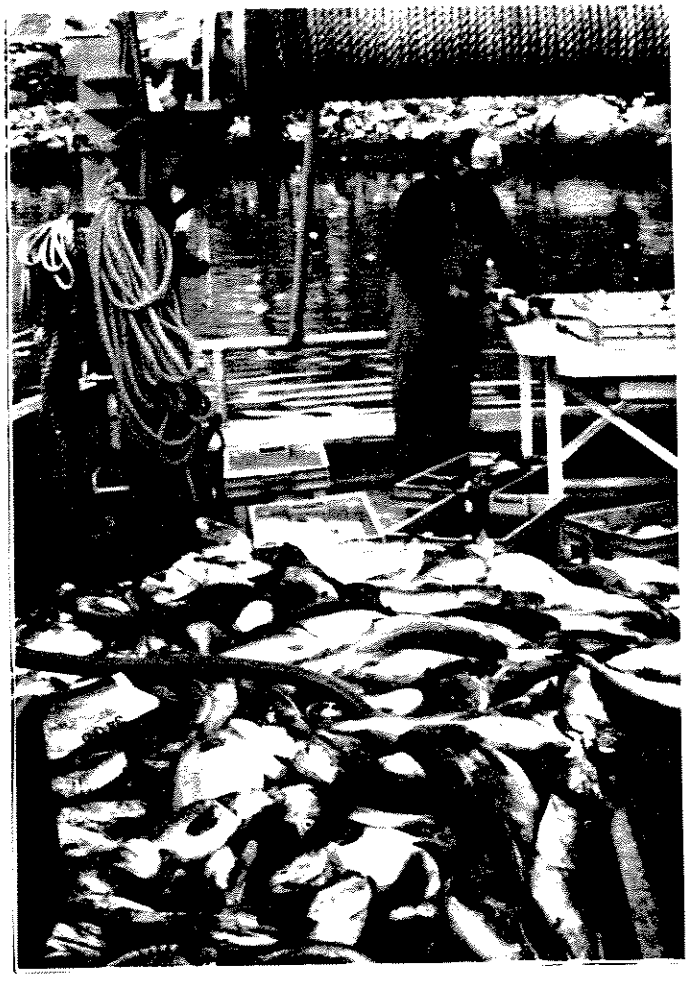

Photo 5. Processing Atlantic cod on board "F.V. Silver Condor"

Once fishing efforts were concentrated in the immediate area of Killiniq, all processing was done directly onboard the "Silver Condor". Gutting, splitting and washing were done on the stern deck and the split cod then lowered to the hold (lower right) and layered with salt. Note the uniform large sizes of fish in the catch.

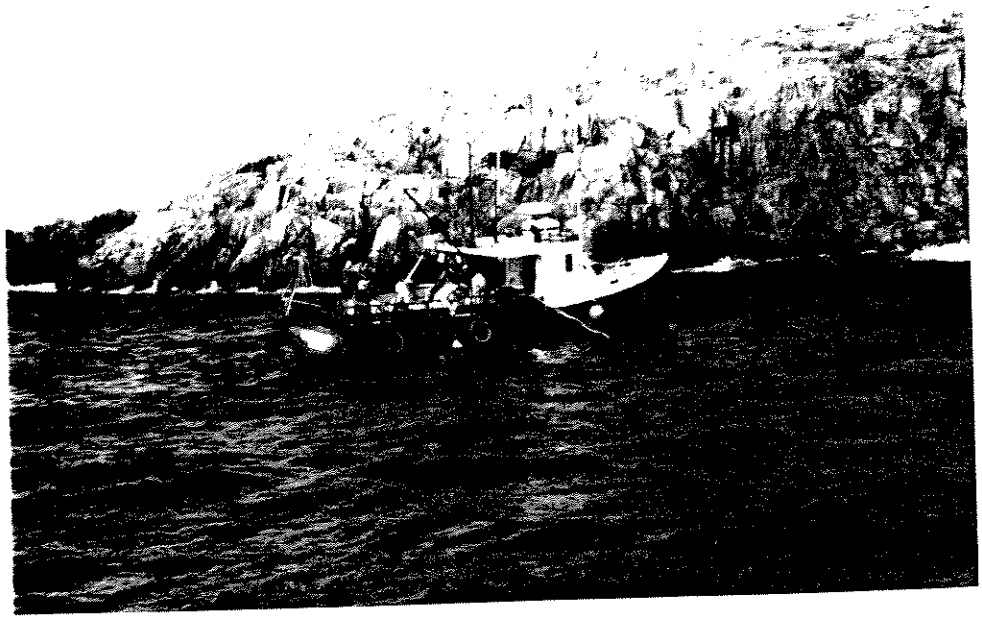

Photo 6. "F.V. Cindy Rogers" retreiving gillnets near Killiniq

Best catches of Atlantic cod during Phase I were taken very close inshore along the south coast of Jackson Island (see figure 8, section D.3). At these locations, the bottom was steeply sloped near the shoreline and depths dropped quickly to more than 60 fathoms. The "Cindy Rogers" being small and maneuverable, was ideally suited to working in such close quarters.

Photo 7. Heavily laden gillnet being retrieved onboard "F.V. Cindy Rogers"

Individual catches of Atlantic cod near Killiniq were, in some cases, quite spectactular. In one case, 2830.1 kilograms of cod were taken from one fleet of four nets in an overnight set.

Photo 8. Atlantic cod, split and cured at Killiniq

The Atlantic cod at Killiniq during Phase I were a superior raw material for a variety of potential products, being of a uniform large size. The quality of the salted product was independently judged to be excellent, although due to the "dryness" of the salt used (section D.4) and the shortness of the curing period, some of the catch was inadequately cured. The thickness of the flesh, evident in this photo, accentuated this problem.

Photo 9. Inuit fisherman preparing fish for salting

The four Inuit fishermen hired during Phase I, became involved in most aspects of the operation including fishing onboard the vessels, processing, and preparing and repairing fishing gears. With their knowledge of the surrounding areas, they provided key advice while navigating the vessels close to the coast.

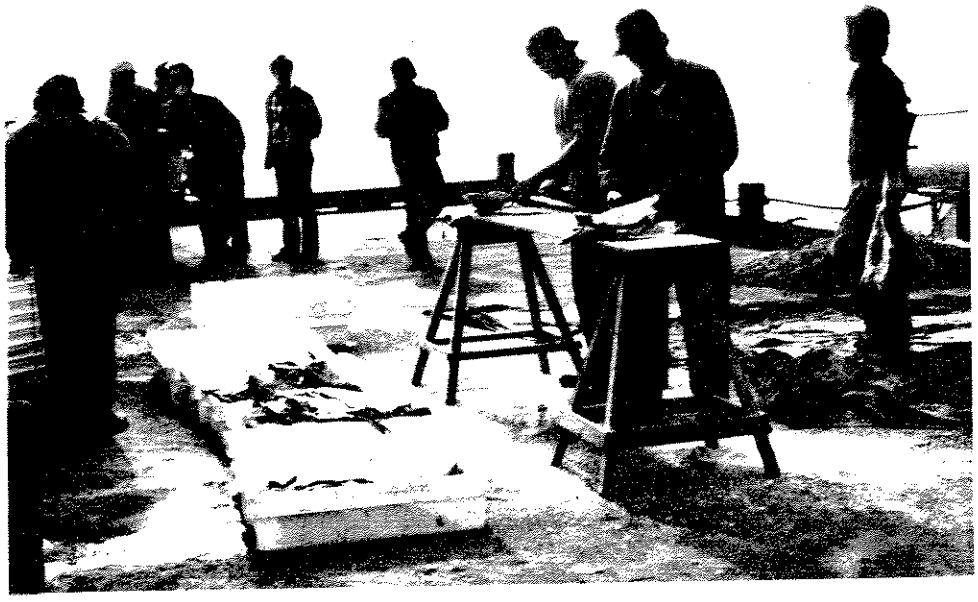

Photo 10. Grading of the salted product prior to sale at Lourdes-de-Blanc-Sablon, Québec

A total of 3337 kg of heavy-salted cod was sold at the completion of the Phase I survey. Over 90% of this product was graded "large" or "extra large".

APPENDIX B - DAILY METEOROLOGICAL RECORDS

The following meteorological records were made at Killiniq between July and September 1983, by M.O.T. personnel at "VAW" Killiniq. (Source: Environment Canada, Canadian Climatological Centre)

APPENDIX C - SET DATA

A complete set of descriptive parameters concerning every fishing effort during Phase I is given in the following table.

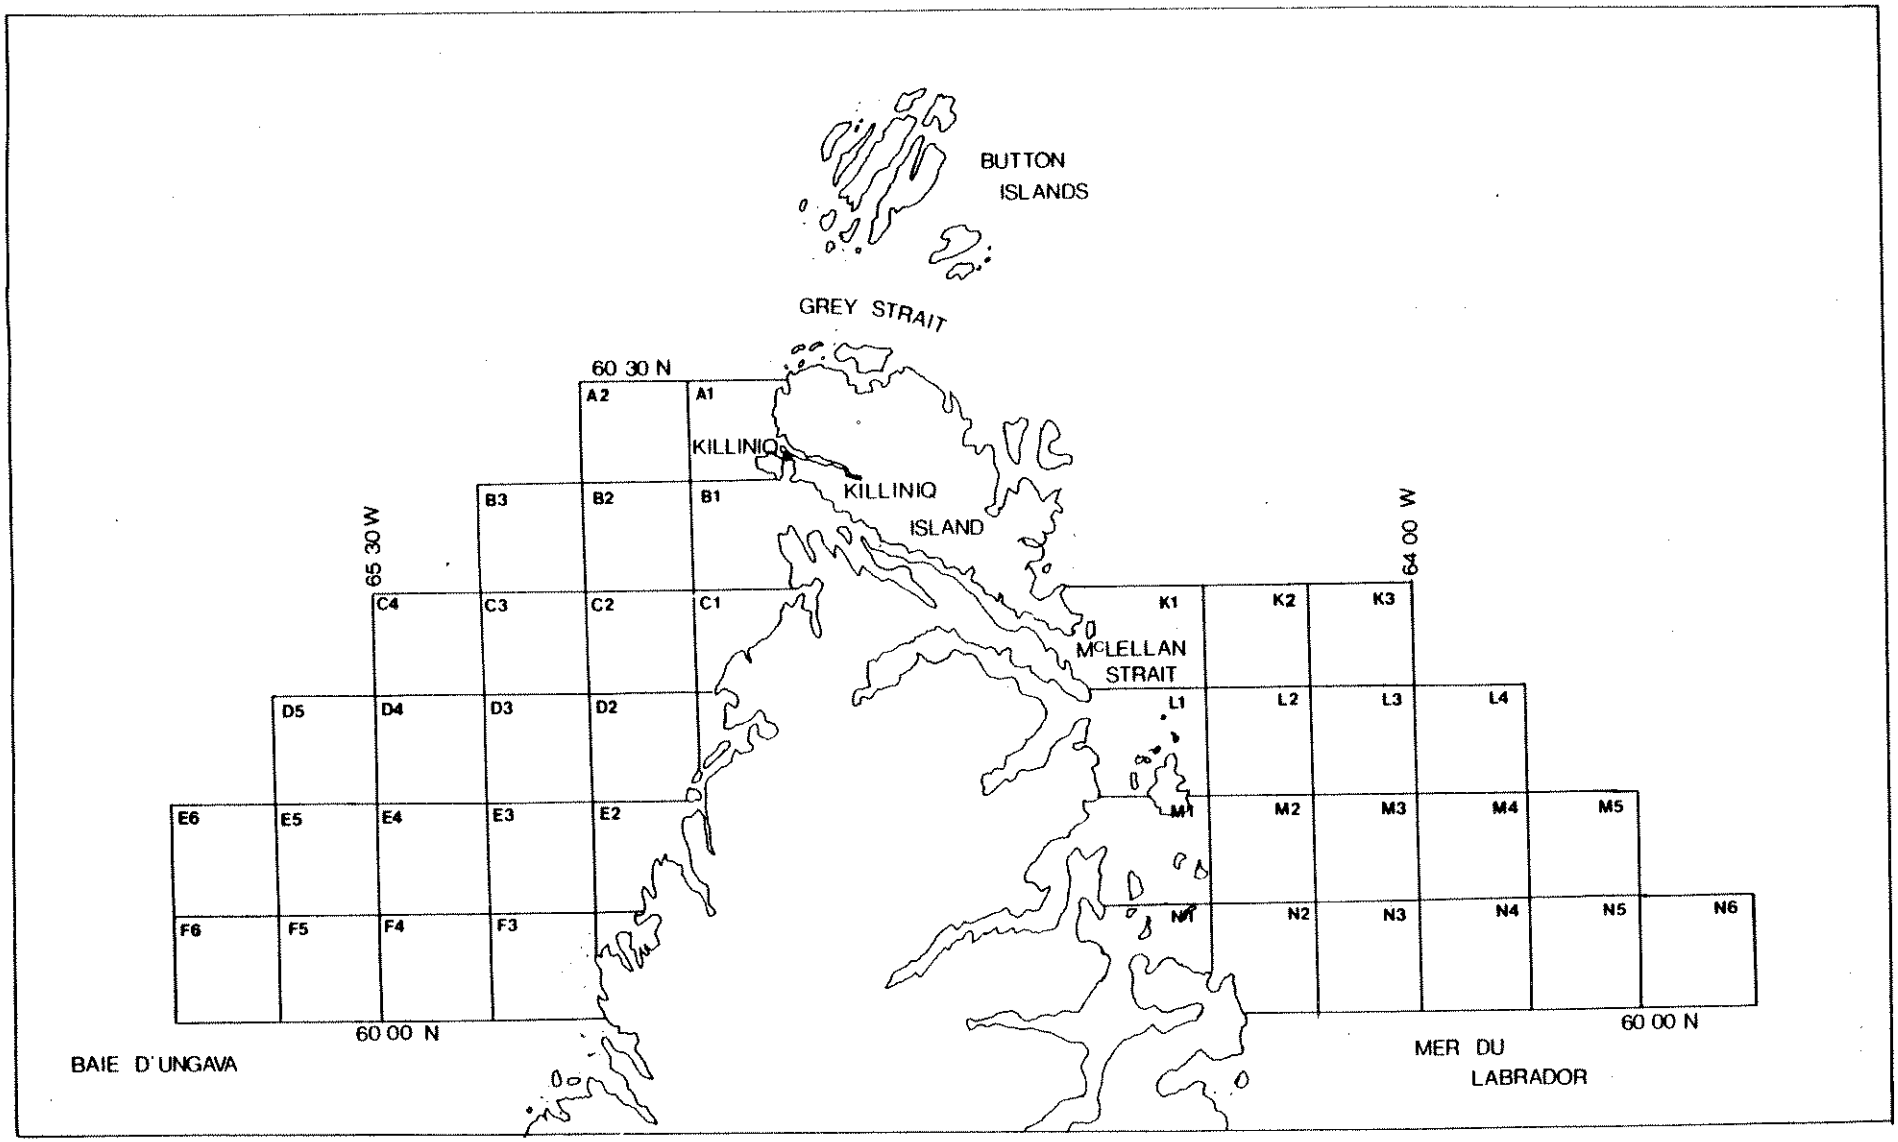
KEY

SET NO. and GEAR TYPE:

- L = longlines
- I = Inuit net
- CP = crab pot
- C = commercial gillnet
- J = jigger (N = Norwegian; NFLD = Newfoundland)

VESSEL:

- CR = "F.V. Cindy Rogers"
- SC = "F.V. Silver Condor"



GRILLE D'ECHANTILLONNAGE DE L' AIRE D'ETUDE, PROJET DES PÊCHERIES DE KILLINIQ, PHASE I

APPENDIX E - LENGTH FREQUENCY DATA, ATLANTIC COD

The following are records of the individual Atlantic cod which comprise the length frequency data base.

KEY

GEAR TYPE/TYPE D'ENGIN

C = commercial gillnet
L = longlines

MESH SIZE/MAILLE:

#S = stretched mesh size in inches
M = mixed sizes of meshes

SEX/SEXE:

M = male
F = female
0 = not sexed

TOTAL LENGTH/LONGUEUR TOTALE: mm

PROJET DES PÊCHERIES DE KILLINIQ - PHASE I (1983)

APPENDIX F - AUTOPSY DATA, ATLANTIC COD

The following are records of the individual Atlantic cod which were autopsied during Phase I.

KEY

SEX/SEXE:

M = male
F = female
0 = not sexed

PARASITES/PARASITES:

# = sample #
0 = no sample

OTOLITH LENGTH/LONGUEUR DES OTOLITHS:

# = maximum length (mm)
0 = not available

LENGTH/LONGUEUR: total (mm)

APPENDIX H - REPORT ON STOMACH CONTENT ANALYSIS

REPORT ON STOMACH CONTENT SAMPLES

KILLINIQ FISHERIES PROJECT

PHASE I

DR. MAX DUNBAR

MARCH 1983

Cod stomachs, Port Burwell, 1983.

Not all, in fact, were cod stomachs; Four were Greenland Halibut.

Gadus morhua	80 samples
Gadus ogac	6 samples
Reinhardtius hippoglossoides	4 samples

1. Gadus morhua stomach samples.

a) fishes.

Myctophum glaciale. By far the commonest fish in the cod stomachs, sometimes over 80 in one stomach. Not all specimens were kept. Found in the following samples (see separate list for sample number and label information):
1, 2, 3, 5, 6, 8, 9, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 27, 29, 30, 31, 32, 33, 34, 35, 36, 37, 44, 45, 48, 49, 50, 51, 53. 54, 55, 56, 58, 61, 62, 63, 71, 72, 74, 75, 77, 79, 88.

Reinhardtius hippoglossoides. One or two (highest number in one stomach - 9) in several stomachs. Found in samples 6, 8, 9, 11, 19, 22, 25, 29, 30, 31, 35, 44, 45, 51, 52, 54, 55, 61, 62, 63, 69, 71, 72, 79.

Lycodes reticulatus. Possibly some belonged to other species of the genus -- many were partly digested -- but reticulatus was certainly identified in the better specimens. It was the only species recorded in Ungava Bay by Dunbar and Hildebrand (1951). A few taken, usually singly in the samples. Found in samples 12?. 14, 18, 29, 30, 41, 44?.

Three large specimens of this species, apparently caught on the longline, were identified.

Ammodytes dubius? One specimen, sample number 2.

Triglops pingeli. Taken in samples 35, 52, 68, 72, 87.

Unidentified fish. Many stomachs contained fish remains so far digested as to defy identification. Samples 15, 16, 17, 18, 20, 22, 30, 35, 36, 42, 44, 45, 46, 49, 50, 51, 52, 53, 56, 57, 59, 61, 64, 66, 67, 69, 73, 75, 76, 78, 79, 87, 88.

[Gadus morhua stomachs, continued]

b) amphipods

Haploops setosa. By far the most abundant. Taken in samples 2, 3, 5, 6, 8, 11, 13, 15, 17, 23, 24, 25, 26, 30, 31, 33, 37, 49, 51, 53, 55, 57, 58, 70, 71, 72, 75, 77, 78, 88.

Anonyx nugax. A few, except for one stomach (no. 43, which contained 112 specimens and nothing else). Samples 3, 16, 43, 44, 51, 64, 67, 72, 75, 79, 88.

Parathemisto libellula. One specimen in sample 16.

Stegocephalus inflatus. One specimen, sample 31.

Gammarus wilkitzkii. One specimen, sample 35.

Unidentified amphipods: Samples 57, 66.

c) Decapod crustaceans

Lebbeus groenlandicus. The commonest decapod in the collection. Samples 41, 44, 45, 46, 48, 49, 51, 52, 53, 54, 59, 60, 62, 67, 68, 70, 75, 81, 85, 87.

Lebbeus polaris. Also fairly anundant. Samples 25, 41, 42, 44, 47, 50, 51, 52, 53, 54, 66, 68, 70, 72, 85, 87, 88. Frequently found in the same stomachs as L. groenlandicus.

Eualius fabricii. Samples 1, 70.

Pandalus montagui. Samples 6, 10?, 12, 21?, 22?, 31, 35, 69, 74, 79.

Sabinea septemcarinata (?) Sample 52.

Spirontocaris spinus.(?). Sample 52.

Spirontocaris lilljeborgi. Samples 59, 60.

Spirontocaris sp. Sample 62.

Sclerocrangon boreas. One specimen, sample 88.

Unidentified shrimps: Many macerated specimens. Samples 4, 5, 8, 9, 14, 15, 16, 20, 28, 29, 30. 31, 33, 34, 37, 47, 48, 50, 55, 56, 57, 60, 61, 62, 63, 67.

[Gadus morhua, continued]

d) Mysidacea.

Boreomysis nobilis. Not common, usually only one per stomach, in samples 2, 12, 14, 35, 37, 48, 88.

e) Isopoda.

Mesidothea sp. entomon?. Sample 54, one specimen.

f) Polychaete worms. A few, all much digested and not identifiabl Samples 2, 20, 46, 52, 74, 85.

g) Holothuria. Not identified: samples 75, 87.

h) Cephalopod molluscs. Not identified. Samples 6, 10, 11, 15, 22, 37, 45, 53, 74.

2. Gadus ogac.

Anonyx nugax (amphipod). A few; samples 65, 76, 86.

Haploops setosa (amphipod). Sample 78.

Lebbeus groenlandicus (shrimp). Samples 65, 78, 83, 84, 86.

Lebbeus polaris (shrimp). Samples 65, 78, 83, 86.

Unidentified polychate: Samples 65, 76, 78.

Triglops sp. (sculpin). Sample 83.

Unidentified fish: Samples 76, 78, 83.

3. Reinhardtius hippoglossoides.

Liparis cyclostigma (lumpsucker). Samples 89, 73.

Triglops sp. (sculpin). Sample 73.

R. hippoglossoides (Greenland halibut). Sample 73 (cannibal).

Myctophum glaciale (lantern fish). Sample 73.

This material shows very much less variety than the stomach contents taken from Atlantic cod at Burwell during the "Calanus" expeditions, which appear to have been a different stock of cod. This lesser diversity is especially remarkable in the decapod crustacea and the amphipods, but is found in all groups.

APPENDIX I - REPORT ON PARASITE SAMPLE ANALYSIS

Killiniq Fisheries

Report on Parasite Samples

Obtained in August 1983

Introduction

This brief report identifies the parasites collected by Makivik personnel during the experimental fisheries program near Killiniq in August 1983. The usefulness of obtaining information on fish parasites in the region is primarily related to marketability of the fish. Codworm (Phocanema decipiens), a major source of economic loss to fisheries in the Gulf of St. Lawrence and Scotian Shelf, was not expected to occur in the Killiniq region and it is important to confirm this. Furthermore, it was considered worthwhile to gather data on any parasites that did occur in order to evaluate their economic or human health significance.

Methods

Parasites were collected from the viscera of Atlantic cod (Gadus morhua) and Greenland cod (G. ogac)between August 21 and August 30, 1983. A total of 44 fish were sampled. The parasites were fixed and preserved in 5% glycerine alcohol and sent to the Institute of Parasitology for further processing. Nematodes were cleared by repeated additions of glycerine alcohol and evaporation. Cestodes were stained and cleared by several routine methods.

Taxonomic keys used in identifying the nematodes were Myers (1975) and Anderson et al. (1974). Cestodes were identified by reference to Wardle and McLeod (1952). A reference collection has been retained for future use.

Results and Discussion

Table 1 lists all parasites identified from the collected material. Data on the fish in which the parasites occurred is available by reference to the code numbers assigned by Makivik.

The parasite species found consisted of two nematodes (Anisakis sp., Thynnascaris adunca) and one cestode (Abothrium gadi). In some publications Thynnascaris adunca is referred to by its synonym, Contracaecum aduncum. It occurs as an adult in the viscera,

frequently the liver, of its host fish and is reported to cause atrophy of the liver in heavily infected cod (Margolis, 1970). Thynnascaris is occasionally found in the flesh of commercial fish, particularly if the nematodes have been allowed sufficient time to migrate there from the viscera after the death of the fish. Thynnascaris was the most common of the parasites encountered in the samples. It is usually acquired by fish feeding upon infected crustaceans or other invertebrates, and can be transmitted from prey fish to their predators.

Anisakis sp. occurs as a larval form in marine fish, and thus the specimens obtained are difficult to identify to the species level. Carried primarily by fish which consume pelagic food such as euphausids, Anisakis has dolphins and porposes as its normal definitive hosts. In common with Thynnascaris, this parasite also is known to damage the liver of its host fish. Anisakis is implicated in human health problems associated with the consumption of raw or pickled fish (often herring) and the medical community now generally refers to the clinical manifestations of this as "anisakiasis". This is further discussed below.

The cestode Abothrium gadi is found as an adult form in the intestine of cod and related fish. It is of no known pathogenic importance to the fish and is of no consequence to human health.

Anisakiasis

Because the two nematodes identified above are listed by Cheng (1976) as genera implicated in anisakiasis, it is perhaps useful to provide some further information here. The phenomenon of anisakiasis first became recognized in the Netherlands during the 1950's and has since become known in other parts of Europe, North America and Japan. Human anisakiasis is generally the result of living nematodes attempting to penetrate the digestive tract (most commonly the stomach) of an individual who has just consumed raw, pickled or undercooked fish contaminated with the parasites. Serious complications are rare, but because of the prevalence of nematodes in many marine commercial fish populations most nations now have adopted regulations to minimize the possibility of further cases of anisakiasis, for example by stipulating that fish must be frozen before pickling. For detailed accounts of cases of anisakiasis and the parasites involved one should refer to the relevant literature (Cheng, 1976; Margolis, 1977; Myers, 1970). One case of anisakiasis has been reported in arctic Alaska (Lichtenfels and Brancato, 1976).

Summary and conclusions

Although only preliminary findings are available to date, at least some interesting information has resulted from the parasite samples obtained last summer. The absence of codworm from any of the samples would appear to endorse the existing view that it does not occur in the Killiniq region. In consideration of the fact that grey seals, the primary definitive hosts for codworm, are absent from the adjacent Labrador and Ungava coasts, this result was to be expected.

The presence of two forms of anisakine nematode (Thynnascaris adunca and Anisakis sp.) in the samples is noteworthy because of the known association of these parasites with human anisakiasis. However, the occurrence of anisakine nematodes is a regular feature of most cod stocks and is only of concern when parasite incidence is high. It would be useful to observe the percentage of heavily infected fish in future work in the region.

As a recommendation for continued work, it should be seen as important that some samples of fish flesh be taken for parasite analyses. In the light of the occurrence of Thynnascaris and Anisakis from visceral samples, it would appear that a follow-up study be carried out to determine whether or not these parasites also may be present in the flesh. Simple procedures for the digestion of fish flesh and recovery of parasites are available and could easily be incorporated into the general work already planned.
